OF THE  
THEORY AND PRACTICE  
OF  
P E R S P E C T I V E.

WHEREIN

The Principles of that most useful Art, as laid down by Dr. BROOK TAYLOR are fully and clearly explained, by Means of moveable Schemes, properly adapted for that Purpose.

The whole being designed as

An Easy INTRODUCTION to the Art of DRAWING in PERSPECTIVE,

AND

Illustrated by a great Variety of Curious and Instructing EXAMPLES.

---

A Figure in a Picture, which is not drawn according to the Rules of Perspective, does not represent what is intended, but something else: so that it seems to me, that a Picture which is faulty in this Particular, is as blameable, or more so, than any Composition in Writing which is faulty in Point of Orthography or Grammar.

Dr. BROOK TAYLOR's Preface.

---

By DANIEL FOURNIER,  
Drawing-Master, and Teacher of Perspective.

T O

Mr. M A R Q U O I S,  
Master of the Military Academy at Noreland,  
near Kensington Gravel-Pits.

S I R,

**T**HE following Treatise of Perspective being drawn up for the use of the noblemen and gentlemen, whose military education you superintend so successfully, it is, I presume, with the strictest propriety that I inscribe it with your name.

It adds greatly to your reputation, that you are the first man who opened, in a private way, an academy of this kind. How very important such institutions are judged by the government, appears from the Royal Academies of Woolwich and Portsmouth, founded under the auspices of his late Majesty King GEORGE II.

The valour of the English has been ever acknowledged, as the French have often experienced to their cost: but it was long observed, that

the military skill of the French officers was far superior to that of the English, and this through want of military academies, where our noble and generous youth might be taught those arts, which only can enable them to shine both in the field and on the ocean.

How useful a member, Sir, you are to society, appears from the excellent pupils you are daily forming : 'tis to your friendship that I owe the great honour I have to instruct them in the art of drawing and perspective. For this, and many other favours from you, gratitude obliges me to wish all imaginable success to your laudable endeavours ; and to assure you, that no one can be with more perfect esteem,

S I R,

Your most humble,

and most obedient servant,

DANIEL FOURNIER.

T H E  
P R E F A C E.

AS Dr. Brook Taylor's Perspective is undoubtedly the most excellent performance of its kind hitherto made public, I chose rather to attempt an explanation of his principles, than to offer any thing of my own, with regard to the theory of this most useful art; and chiefly because the generality of those who apply themselves to the study of that treatise, without being first acquainted with geometry, find great difficulty in conceiving the author's design, as all his schemes are drawn in plano: I have, to obviate this difficulty, introduced moveable schemes in the following work, so contrived, as to be raised up and placed according as the nature of the problem may require.

In the practical part, which begins at page 32, I have defined and made use of the terms, ground line, horizontal line, &c. This I did for the convenience of those who may have already learned the theory of perspective, from such authors as have treated thereon agreeable to these definitions, and because painters commonly use the horizontal line as the boundary of the picture.

As the art of perspective consists in the knowledge of truly representing an object according to its natural appearance, so whatever is not drawn agreeable the rules thereof, cannot possibly represent what is intended, but something else: it is true, that as the art of painting consists of two parts, the inventive and the executive, the former may indeed be varied according to the taste  
and

and genius of the artist, in the disposition of the parts of his subject ; but the latter is wholly confined and strictly tied to the rules of art, and therefore in this the artist is not to take any liberties whatsoever ; for what is perfectly just in the real original objects themselves, can never appear defective in a picture, where those objects are represented according to the true rules of perspective.

Notwithstanding the principles upon which Dr. Taylor has founded his treatise seem so very obvious as not to admit of any objection ; yet some modern writers upon this subject have so far deviated from his theory, as to inform us, that a circle, when viewed in an oblique position, cannot possibly take the appearance of a true mathematical ellipsis. I shall not at present enter into a confutation of the reasons they give to support the truth of this extraordinary assertion, but only point out wherein (I think) they are mistaken. That the oblique section of a cone may be an ellipsis, is certainly true : I say may be an ellipsis, because in some cases it may be an hyperbola ; wherefore, if the cutting plane be supposed to be the plane of the picture, the representation of a circle thereon must be either a circle, ellipsis, or a right line, and that according to the different situations of the original circle with regard to the plane of the picture ; if after having found the elliptical representation of an original circle, we find that of its center, it will not coincide with the center of the ellipsis ; and this I apprehend may have deceived those who have imagined the oval representation of an oblique circle would not be of equal curviture in opposite parts of its circumference.

O F

# L I N E A R P E R S P E C T I V E .

**I**N order that the learner may form a clear idea of the investigations relating to the theory of *Perspective* contained in the ensuing pages, it may be necessary to premise the following geometrical Definitions and Problems.

## D E F I N I T I O N S .

1. *Magnitude* is whatever is extended, and therefore may be conceived to be contained or limited by some certain term or terms.
2. A *point* is that which has no parts, consequently of itself no magnitude, and may be considered as indivisible.
3. A *right line* is the nearest distance between two points.
4. If two right lines inclined to each other be produced till they meet, they will form a plane or *right lined angle*. Thus the angle formed by the lines BD, CE, Plate I. Fig. 1. produced, is denoted by BAC.

N. B. An angle being generally denoted by three letters, the middle one always represents the angular point.

5. When a strait line stands on another, so that it does not incline to one end more than the other, but makes the angles on both sides equal; then are these called *right angles*: and the lines are said to be *perpendicular* to each other; as BD Plate I. Fig. 2. is perpendicular to FE.

6. Every angle greater than a right one, is called an *obtuse angle*; and every angle less than a right angle, is called an *acute angle*.

7. A plane surface terminated by three right lines, is called a *plane triangle*.

8. When the three sides of a triangle are equal, it is called an *equilateral triangle*.

9. When only two sides are equal, an *isosceles triangle*.

10. When the three sides are unequal, a *scalene triangle*.

11. When one angle of a triangle is a right angle, it is called a *right angled triangle*.

12. Any one side of a triangle may be called the *base*, and the angular point opposite to the base is called the *vertex*.

13. In a right-angled triangle, the side opposite to the right angle is called the *hypotenuse*.

14. A plane contained by four right lines, is called in general a *quadrilateral figure*; and when the four sides are equal as well as the four angles, it is called a *square*.

15. If the four angles are equal, and only the opposite sides, a *rectangle*.

16. If the opposite angles are only equal, and the opposite sides, a *parallelogram*.

17. A plane figure of above four sides is called, in general, a *polygon*.

18. A *circle* is a plane figure bounded by one continued line called the *circumference*, which is every where equally distant from a point within the circle, called the *center*.

19. Any line drawn from the center to the circumference is called a *radius*; the double of which is the *diameter* of the circle.

20. The measure of an angle is the arc described from the angular point as center with any radius, and terminated by the lines which form the angle.

21. A line which touches a circle in one point only, is called a *tangent*; and the point where it touches, the point of *contact*.

22. A polygon is called *regular*, when all its sides are equal as well as all its angles; and *irregular*, when they are not equal.

23. A polygon is said to be *inscribed* in a circle, when all its angles touch the circumference; and *circumscribed* about a circle, when all its sides touch the circle.

Polygons are distinguished by the number of their sides, viz.

5 Pentagon,	9 Enneagon,
6 Exagon,	10 Decagon,
7 Eptagon,	11 Ondecagon,
8 Octagon,	12 Dodecagon,

PROBLEM I.

*To divide a given right line into two equal parts.*

Let the line given be AB, Plate I. Fig. 3. Set one foot of the *compasses* in A, and with any convenient distance sweep two *arches* one above and the other below the given *line*; then set one foot of the *compasses* in B, and with the same distance as before cross the aforesaid *arches*, join the points of intersection with a right line, and it will cut AB in two equal parts.

PROBLEM 2.

*To raise a perpendicular from any point proposed, in a given right line.*

Let the given line be AB, Plate I. Fig. 4, and the *perpendicular* to be raised from the point C; to do which, set off two equal distances from the point C, as CR, CS: then the *compasses* being opened to any convenient distance greater than CR or CS, with one foot of the *compasses* in the point R describe the *arch* DE: then with the same extent, and one foot of the *compasses* placed in the point S, describe the *arch* FG; then

## 4 LINEAR PERSPECTIVE.

draw from C a right line through the intersection of the two *arches* FG, DE, and it will be the *perpendicular* required.

### PROBLEM 3.

*To let fall a perpendicular from a point assigned, to a given right line.*

Let AB, Plate I. Fig. 5. be a right line given, and C the point from whence the *perpendicular* must fall.

Set one foot of the *compasses* in C, and opening them to a proper distance describe the arch RS; then by Prob. 1, divide RS into two equal parts in D, join the points C, D, and CD will be the *perpendicular* required.

### PROBLEM 4.

*To draw a right line parallel to a given right line, and also through a point given.*

Let AB, Plate I. Fig. 6, be the given line, and C the point given. From C let fall, by the last Problem, the perpendicular CD upon the line AB. Take any point, as E in AB, in which set one foot of the *compasses*, and with an opening equal to CD, describe an *arch* FG; lay a ruler, so as just to touch this *arch* and the point C, then draw the line CH, it will be the *parallel* required.

### PROBLEM 5.

*To divide a given right line into any number of equal parts.*

Let AB, <sup>Plate Fig</sup> ~~Fig. I. Plate~~ 7, be the given line.

From the point A draw a right line AC at pleasure; from the point B draw a right line BD parallel to AC, set off along AC and BD from the points A and B, as many equal parts AE, EF, FG, &c. and BK, KL, LM, MN, &c. towards C and D respectively, as are one less than the number into which you intend the given line to be divided; join the last point in AC with the first in BD, and also join the other points I, L, G, N, F, O, &c. and the right lines KK, IL, HM, GN, &c. will divide AB into the desired number of equal parts at the points k, i, h, g, &c.

## LINEAR PERSPECTIVE.

### PROBLEM 6.

*To divide a given angle ACB, Plate I. Fig. 8, into two equal parts.*

From the angular point C as center, describe an arch with any radius, meeting the legs of the angle at A, B : from these points, as centers, describe two *arches* with the same radius, so as to intersect each other at D ; then the line drawn through this intersection and the angular point C, will bisect the given angle.

### PROBLEM 7.

*To draw a line CA, so as to make an angle ACB, with a given line CB, equal to a given angle a c b, Plate I. Fig. 9.*

From the points C, c, as centers, describe two arches with any radius at pleasure : make the arch AB equal to the arch a b ; and the line drawn through the points C, A, will form the angle required.

Note, The circumference of every circle, whether great or small, is supposed divided into 360 equal parts, called degrees, each degree into 60 equal parts, called minutes. Hence a quadrant, or the measure of a right angle, is 90 degrees, being the fourth part of the circumference ; a semicircle, or the measure of two right angles, is 180 degrees, being the one half of the circumference.

### PROBLEM 8.

*To describe the circumference of a circle, through three given points A, B, C, Plate I. Fig. 10.*

Join these points by two lines AB, BC, bisect them with the perpendiculars DO, EO ; their point of intersection O, will be the center of the circle desired.

### PROBLEM

## LINEAR PERSPECTIVE.

### PROBLEM 9.

*To inscribe a square in a circle. Plate I. Fig. 11.*

Draw the diameter AB, to which draw the diameter CD perpendicular; then the lines joining the extremities of these diameters will be the square ABCD required.

### PROBLEM 10.

*To inscribe a regular polygon of a given number of sides in a circle.*

Draw two radii from the center of the proposed circle, making an angle equal to the *angle at the center of a polygon* answering to the assigned number of sides (as in the table annexed): join the two points in the circumference, where the radii intersect it, add that line or *chord* will be the side of the required polygon.

A TABLE of regular POLYGONS.

Polygon.	Angle at the Center.	Angle made by the Sides.
5	72	108
6	60	120
7	$51\frac{3}{4}$	$128\frac{3}{4}$
8	45	135
9	40	140
10	36	144
11	$32\frac{8}{11}$	$147\frac{3}{11}$
12	30	150

They

The angle at the center of a regular polygon is found by dividing 360 degrees by the number of the sides : thus 360 divided by 5 gives 72 degrees for the angle at the center of a Pentagon ; and 360 divided by 6 gives 60 degrees for the angle at the center of an Exagon.

But the angle made by two adjacent sides of a polygon is found by subtracting the angle of the center from 180 degrees : thus from 180 degrees take 72, there remains 108 degrees, which is the angle made by the sides of a Pentagon ; and if from 180 we take 60, (the angle at the center of an Exagon) there will remain 120, the angle made by the sides of an Exagon : in the same manner may the remaining numbers in the third column of the foregoing table, be found.

Having furnished the reader with the most necessary geometrical Problems, for the understanding of Perspective, we shall next proceed to the Definitions thereof.

#### DEFINITION I.

In order to have a clear idea of the principles of this art, we are to consider that a picture drawn perfectly true, and placed in a proper position, ought so to appear to the spectator, that he should not be able to distinguish the representation from the real original objects actually placed where they are represented to be. To produce this effect, it is necessary that the rays of light ought to come from the several parts of the picture to the spectator's eye with the same circumstances of direction, strength of light and shadow, and colour, as they would do from the corresponding parts of the real objects seen in their proper places. Thus, Plate II. Fig. 1. let O be the spectator's eye, FH the plane of the picture, which, for more easy conception, we may suppose to be transparent, ABCDE an original cube ; then if we imagine lines to be drawn from O to every part (in view) of the solid ABCDE, their intersection with the plane FH will mark thereon the representation a b c d e of the original figure ABCDE.

2. *Cone of rays.* Lines drawn from the several parts of any figure, and continued so as to pass through one and the same point, constitute a cone of rays; and when that point is considered as the eye of a spectator, it is called the *optic cone*.

3. *Ichnography.* When a system of rays (parallel to each other and perpendicular to the horizon) coming from the several points in any figure, is cut by a plane parallel to the horizon, the projection thereon is called the *ichnography of the said figure*.

4. *Orthography.* When a system of rays (parallel to each other and to the horizon) coming from the several points in any figure, is cut by a plane perpendicular to the horizon, the projection thereon is called the *orthography of the said figure*.

These are the *common* definitions of the terms *ichnography* and *orthography*; but in the following pages we shall use them to signify any two projections that are made by systems of parallel rays, when those systems are perpendicular to each other, and to the planes on which the projections are made, without having any regard to their situation with respect to the horizon.

5. *Schenography.* When the optic cone is cut by a plane, the representation of the proposed figure thereon is called the *schénography* thereof. It is evident that the shadows of figures are this projection, when the light is considered as a single point: though in the case of the sun or moon, that point being at an infinite distance (as to all sense), the projecting rays are parallel to each other.

6. *Point of sight* is the vertex of the optic cone, or it is that point where the spectator's eye should be placed to look upon the picture.

7. *Distance of the picture.* The point in which a perpendicular let fall from the *point of sight* upon the picture cuts it, is called the *center* of the picture; the distance between the *center* and *point of sight* is called the *distance of the picture*.

8. *Directing plane* is that plane which passes through the *point of sight* parallel to the picture.

9. *Original object*; the real object (whether it be point, line, surface, or solid,) placed in the situation it is represented to have by the picture.

10. *Original plane*. The plane wherein is situated any original point, line, or plane figure, is called the *original plane*.

11. *Intersection of an original line* is that point wherein the said line (continued if need be) cuts the picture.

12. *Intersection of an original plane* is that line wherein the said plane cuts the picture.

13. *Directing point of an original line* is that point wherein the said line cuts the *directing plane*. And a right line joining the directing point and point of sight, is called the *director* of that original line.

14. *Directing line of an original plane* is that line wherein an original plane cuts the directing plane.

15. *Parallel of an original line* is a right line drawn through the point of sight parallel to the said original line.

16. *Parallel of an original plane* is a plane passing through the point of sight parallel to the said original plane.

17. *Vanishing point* is the point where the parallel of any original line meets the picture, and is called the *vanishing point* of that line; the distance between the vanishing point and the point of sight is called the *distance* of that vanishing point.

18. *Vanishing line* is that line wherein the parallel of any original plane intersects the picture. From the point of sight let fall a perpendicular to the vanishing line; the point where that vanishing line is so cut is called the *center* of it, and the distance between the center and point of sight is called the *distance* of that vanishing line.

19. *Representation of any figure* is the projection of that figure. In order to comprehend the sense of these definitions more fully, let the planes ABIC, DEO, Plate III. Fig. 1. be so raised up as to stand parallel to each other, and bring the plane ACO parallel to the plane FGH: this done, imagine the plane ABIC to be the surface of the picture, O to be the point of sight, (Def. 6. Perspective) the plane DEO to be the directing plane, (Def. 8.) FG to be an original line (Def. 9.) in the original plane FGH, (Def. 10.) cutting the picture in BI and the directing plane in DE: and let ACO cut the picture in the line AC, and suppose OV to be drawn parallel to the original line FG, and cut the picture in V: and let FG (produced) cut the picture in B, and the directing plane in D; then is B the intersection of the original line FG, (Def. 11.) D its directing point, (Def. 13.) and V its vanishing point, (Def. 17.) and OD its director, (Def. 13.) and OV is the distance of the vanishing point V (Def. 17.); BI is the intersection, (Def. 12.) DE the directing line, (Def. 14.) ACO the parallel, (Def. 16.) and AC the vanishing line (Def. 18.) of the original plane FGH. From O let fall a line perpendicular upon the vanishing line AC, and the point wherein the said perpendicular meets AC, as S, will be the *center* of the picture, (Def. 18.) and SO will be the distance of the vanishing line AC (Def. 18.).

#### AXIOM 1.

The common intersection of the two planes is a straight line.

#### AXIOM 2.

If two straight lines meet in a point, or are parallel to one another, there may be a plane passing through them both.

#### AXIOM 3.

If two parallel straight lines are cut by a third line, they will all three be in the same plane; that is, a plane passing through any two of them will also pass through a third.

#### AXIOM

AXIOM 4.

Every point in any straight line is in any plane that line is in.

THEOREM 1.

A line drawn from the center of the picture to the center of a vanishing line, is perpendicular to that vanishing line.

DEMONSTRATION.

Raise up the plane AC (Plate III. Fig. 2.) perpendicular to the plane of the picture AFG; draw OC perpendicular to AF, and move the triangle OSC about OC as an axis, until its base CS is perpendicular to a given vanishing line, as AB; then will OS be perpendicular to ASB, and consequently (Def. 18.) S is the center of the vanishing line proposed.

COROLLARY.

The distance OS of any vanishing line ASB, is the hypotenuse of a right-angled triangle, whose legs are the distance of the picture OC, and the distance CS between the center of that vanishing line and the center of the picture.

THEOREM 2.

The perspective representation, or projection of any object, is the same as the ichnographic projection of it on the plane of the picture, the point of sight being the vertex of the optic cone.

DEMONSTRATION.

For, by the explanation of the principles in Definition 1. the light must come to the spectator's eye O, (Plate II. Fig. 1.) in the same direction from any point *a* of the projection as it would do from the corresponding point A of the original object; therefore it is evident that the rays *a*O and AO are in one and the same straight line. Whence it follows that the projection *a* is the intersection of the picture with the ray AO, and the

whole projection *abcde* is the schenography of the original figure *ABCDE*, made by the optic cone *OABCDE*, whose vertex is the point of sight *O*.

## COROLLARY 1.

The projection of a straight line is a straight line. For conceive a plane passing through the point of sight, and the original line to intersect the picture, it is then evident that the intersection can only be a straight line. As *de* is the intersection of the picture with the triangle *ODE*, and consequently a straight line (by Ax. 1.).

## COROLLARY 2.

The original of a projection may be any object that will produce the same cone of rays. Thus the original of the projection *de* may be any line *de*, which produces the optic cone *ODE*, as well as the line *DE*.

This being so, it may reasonably be asked, whence it happens that figures drawn on a picture appear to be what they are designed to represent. The reason is, because the mind has acquired a habit of judging objects, that are so and so related, have such and such colours, and are so and so enlightened and shaded, to be of such a shape and alike situated. These circumstances are all of them necessary to make a picture complete, though the simple drawing is sometimes almost sufficient, upon account of the relation of the parts; as in a pavement, where all the stones appear to be square, though they are represented by very irregular figures. I say, it is the relation of the parts which produces this effect; for the representation of any one of the single squares would hardly appear to be square, were there no other objects to bias the judgment by their relation to it.

## THEOREM 3.

The projection of a straight line not parallel to the picture, passes thro' both its intersection and vanishing point.

DEMON-

DEMONSTRATION.

Imagine an indefinite plane (passing through the point of sight and the original line) to cut the picture, then it is very obvious that in the line which forms their intersection, that of the original line with the picture will always be found : but by Def. 17. the line determining the vanishing point will also be in this plane, therefore the projection of an original line FG (Plate III. Fig. I.) passes through its intersection B and vanishing point V.

This Theorem being the principal foundation of all the practice of *perspective*, the learner would do well to make it very familiar to him. In order to which I have again represented the meaning of it in Plate II. Fig. 1. where the projection *bc* meets the original line BC in its intersection K, and passes also through its vanishing point V, which is produced by its parallel OV.

N. B. When the original line itself passes through its vanishing point, the whole projection of it will be that point ; so that in that case the line may be said to vanish : this is one reason for using that term. Another reason is, that the further any object is off upon any line, the smaller is its projection, and, at the same time, the nearer to this point, and when it comes into this point, its magnitude will entirely vanish, because the original object is at an infinite distance. This is easily conceived, by imagining a person going from you in a long walk, who appears to be smaller and smaller the further he goes. The reason of this diminution will appear from the following *Corollaries*.

COROLLARY I.

Projections of original lines that are parallel to each other, but not to the picture, pass through the same vanishing point : for they have but one parallel common to them all, and consequently but one vanishing point.

As

As in Plate II. Fig. I. where the projection  $da$  and  $cb$  of the parallel lines DA and CB meet in their common vanishing point V.

COROLLARY 2.

The center of the picture is the vanishing point of lines perpendicular to the picture.

THEOREM 4.

The projection of an original line parallel to the picture is also parallel to that original line.

DEMONSTRATION.

Imagine a triangular plane, whose vertex is at the spectator's eye, and its base the proposed original line, to be cut by the picture. It is evident the representation upon the picture will be parallel to the base of this triangular plane, because the picture is supposed to be so; therefore if EF, Plate III. Fig. 3. be the picture, AB an original line parallel to it, then will its projection  $ab$  be parallel to the original AB, O being the point of sight.

COROLLARY 1.

Lines parallel to one another, and to the picture, are projected into lines parallel among themselves. Thus  $ab$  and  $dc$  are parallel to each other, and to their originals AB and CD.

COROLLARY 2.

The projection  $abcd$  of any plane figure ABCD parallel to the picture, is similar to its original. For draw AC and  $ac$ , then will the triangles ACB,  $acb$ , be similar, as will also the triangles ADC,  $adc$ , consequently ABCD and  $abcd$  are similar.

COROLLARY 3.

$AB : ab ::$  distance of the picture : distance between the point of sight and the plane of the original figure; that is, (OgG being drawn perpendicular to those two planes)  $AB : ab :: Og : OG$ .

THEOREM

THEOREM 5.

The projection of a line is parallel to its director. For the lines OF, OG, OD, *fg.* (Plate III. Fig. 1.) are all in the same plane; but the directing plane ODE is parallel to the plane of the picture ABIC (Def. 8.); therefore the director OD is parallel to the projection *fg.* Eu. 11. 16.

COROLLARY 1.

The projections of lines that have the same director are parallel to each other.

COROLLARY 2.

If the original line is parallel to the picture, its director is so too, and consequently is in the parallel of any plane passing through that original line; and therefore the vanishing line of that plane, and the projection of the line are parallel to one another.

THEOREM 6.

The vanishing line, intersection, and directing line of any original plane, are parallel to each other.

For the planes OVC, DFH, (see the last Figure) are parallel, (Def. 16.) as also ODE and CAB (Def. 8.); therefore the vanishing line CV, intersection IB, directing line ED, are parallel to each other.

COROLLARY.

The triangles OfV, DOF, are similar, and  $DO = BV$ , therefore  $fV : VO :: BV : DF$ .

THEOREM 7.

All lines in any original plane have their vanishing points in the vanishing line of that plane.

DEMONSTRATION.

For as all the original lines are in the same plane, the lines which determine their vanishing points, will intersect the picture in the vanishing line of the original plane.

COROLLARY.

## COROLLARY 1.

Original planes parallel to each other have the same vanishing line.

## COROLLARY 2.

The vanishing point of the common intersection of two original planes, is the common intersection of their vanishing lines.

## COROLLARY 3.

The vanishing line of a plane perpendicular to the picture, passes through the center of the picture.

## THEOREM 8.

Intersections of all lines in the same original plane, and also the line which determines the intersection of that original plane with the picture, are in that plane.

This needs no DEMONSTRATION.

## COROLLARY 1.

The intersection of two original planes, which is not parallel to the picture, being produced, will intersect the picture in that point which is the common intersection of the two planes therewith.

## COROLLARY 2.

If the common intersection of several planes is parallel to the picture, then those planes have parallel intersection therewith, and have also parallel vanishing lines.

## PROBLEM I.

Having given the center and distance of the picture, to find the projection of a point, whose seat\* on the picture, with its distance from it, are given.

Let  $O$  be the spectator's eye, Plate III. Fig 2.  $S$  the center of the picture, and  $b$  the given seat of the original point  $A$ ; then if we imagine a

\* By seat on the picture, we mean that point wherein a perpendicular falling on the picture from the point to be projected, intersects it.

line drawn from O to A, it will cut the plane of the picture somewhere in that line which joins the center of the picture and seat of the original line, as at  $a$ , which is therefore the representation of the point A, by Theo. 2. The triangles  $Aab$   $OaS$  are similar; whence  $Sa : ab :: SO : Ab$ .

## COROLLARY 1.

The point A may be found by a scale and compasses, dividing the line  $Sb$  in  $a$ , so that  $Sa$  may be to  $ab$ , as the distance of the picture OS, is to the distance  $Ab$  of the original point from its seat  $b$ .

## COROLLARY 2.

By this Problem the projection of any right line may be found; for it is no more than finding the projection of any two points therein, and drawing a right line through those two projections.

## PROBLEM II.

To find the projection of a line, its vanishing point and distance; having given its seat, intersection, and the angle it makes with its seat, and the center and distance of the picture.

Let W (Plate IV. Fig. 1.) be a point in the given line, E its seat on the picture, and D its intersection.

Make SO equal to the distance of the picture, draw SV parallel to DE and perpendicular to SO, join the center of the picture and seat of the point W by drawing ES; then it is evident that the projection of W will be in this line: but to determine the exact place, we must divide ES in the proportion of WE to SO, which may be done thus: Make  $ET = EW$ ,  $SM = SO$ ; draw TM, and the point of intersection  $w$  will be the place required: join the points D,  $w$ , and  $Dw$  will be the indefinite representation of the line proposed. If from the point of sight, a right line be drawn parallel to DW, it will intersect the picture in the vanishing point thereof, and its distance will be equal to OV.

D

COROLLARY

## COROLLARY 2.

If the vanishing point and intersection of the original line DW be joined by a right line, it will cut ES in *w*, the projection of the original point W.

## PROBLEM III.

Having given the projection of a line, and its vanishing point, to find the projection of the point that divides the original line in any given proportion.

Let AB (Plate IV. Fig. 2.) be the given projection of the line to be divided, and V its vanishing point. Draw at pleasure VO and *ba* parallel to it; and through any point V of the line VO, draw OA and OB cutting *ba* in *a* and *b*. Divide *ab* in *c* in the proportion given, and draw Oc cutting AB in C. Then shall C be the projection sought, the original of BC being to the original of CA, as *bc* is to *ca*.

For OV being parallel to *ba*, *ba* may be considered as the original line, and OV as its parallel, and consequently O as the point of sight, and *aO*, *bO*, *cO*, as visual rays projecting the points A, B, C.

## COROLLARY.

$CA \times BV : CB \times AV :: ca : cb$ ; for draw *ef* through C parallel to *ab*, then we shall have

$$\left. \begin{array}{l} AC : AV :: eC : OV \\ BV : CB :: OV : Cf \end{array} \right\} \text{whence } AC \times BV : AV \times CB :: eC : Cf :: ca : cb.$$

Therefore the point C may be found by a scale and compasses, making  $CA : CB :: AV \times ca : BV \times cb$ .

## PROBLEM IV.

Having the projection of a line, and its vanishing point, from a given point in that projection, to cut off a segment, that shall be the projection of a given part of the original of the projection given.

Let

Let AB (Plate IV. Fig. 3.) be the projection given, V its vanishing point, and C the point from whence is to be cut off the segment. Draw at pleasure VO, and *abc* parallel to it, and from any point O in VO, draw OA, OB, OC, cutting *ab* in *a*, *b*, *c*. Make *cd* to *ab*, as the given part is to the original of AB, and draw Od cutting AB in D: then will CD be the segment sought.

The Demonstration of this problem is obvious from that of the foregoing one.

## COROLLARY

The point D may be found by a scale and compasses, making  $DC : DV :: dc \times AB \times CV : ab \times AV \times BV$ . For, per last Prob.

$$\left. \begin{array}{l} AB \times BV : AV \times BC :: ab : bc. \\ BC \times DV : BV \times CD :: bc : dc. \end{array} \right\} \text{whence } AB \times CV \times DV \times dc = AV \times BV \times CD \times ab.$$

and therefore  $DC : DV :: dc \times AB \times CV : ab \times AV \times BV$ .

N. B. The foregoing Problem may be considered as a particular case of this, *viz.* when the point C in this coincides with one of the points A or B.

## PROBLEM V.

Having given the center and distance of the picture, to find the vanishing line (with its center and distance) of a plane, whose intersection is given, with the angle of its inclination to the picture.

Let C (Plate III. Fig. 2.) be the center of the picture. Draw CG parallel to the intersection of the original plane with the picture, and equal to the distance of the picture, and from C erect the indefinite right line CS perpendicular to CG; draw GS, making an angle SGC equal to the complement of the angle of inclination of the original plane to that of the picture; draw through S the right line ASB. Then will ASB be the vanishing line sought, S its center, and GS its distance.

Because GC=CO, and the angle GSC equal to the given inclination of

the original plane and picture (by construction), it is evident that the right angled triangle GCS is equal to the moveable right-angled triangle COS; therefore, by Defin. 18. ASB is the vanishing line, and S its center.

N. B. Taking GC for radius, CS is the cotangent, and GS the cofecant of the inclination of the original plane to the picture.

#### PROBLEM VI.

Having given the interfection of an original plane, with its vanishing line, its center and distance; to find the projection of any line in the original plane, having the original figures drawn out in their just proportions.

Let DF (Plate IV. Fig. 4.) be the interfection given, HG the vanishing line, and S its center. Draw SO perpendicular to GH, and equal to the distance of the vanishing line GH, and let the space X be the original plane, seen on the reverse, as objects appear in a looking-glass; the space Y being the parallel plane in the same manner folded down on the picture: and let AB be the original line whose projection is sought. Let AB cut the interfection in D, and draw OG parallel to AB, cutting the vanishing line in G. Draw DG, which will be the indefinite projection of AB. Through A and B draw at pleasure AC and BC meeting in C, and in the same manner find their indefinite projections FI, and EH, cutting DG in *a* and *b*. Then will *ab* be the determinate projection of AB, *a* being the projection of the extremity A, and *b* the projection of the extremity B.

#### OTHERWISE,

Suppose KL to be the original line given. Having found its indefinite projection QG, as before, draw OK and OL, cutting it in *k* and *l*, which will be the projections of the extremities K and L.

#### Otherwise, by the DIRECTORS,

Let DF (Plate IV. Fig. 5.) be the interfection given. And let the original plane be folded down on the picture, so as to bring the directing line into the plane HI, the distance between AF and HI being equal to the distance

distance of the vanishing line given. Let also  $O$  be the point of sight brought into the picture at the same time along with the directing plane  $HIO$ . To find the indefinite projection of any original line  $AB$ , continue it till it cuts  $EF$  in  $F$ , and  $HI$  in  $G$ ; then draw  $OG$ , and  $Fa$  drawn parallel to it will be the indefinite projection sought. Then finding in the same manner the indefinite projection  $Ed$  of any other line,  $AD$  passing through  $A$ , by its intersection with  $Fa$  is got the projection  $a$  of the extremity  $A$ . And in the same manner is got the other extremity  $b$ ; or those extremities might be found by drawing lines from  $A$ , and from  $B$  to  $O$ , as in the foregoing construction.

To prove the truth of these operations, imagine the figures (Plate IV. Fig. 4.) to be folded in  $DF$  and  $HG$ , and (Plate IV. Fig. 5.) in  $EF$  and  $HI$ , till the original plane, its parallel, and the directing plane, and along with them the point of sight  $O$ , come into their proper places. Then you will find, that  $D$  (Plate IV. Fig. 4.) and  $F$  (Plate IV. Fig. 5.) will be the intersection of  $AB$ , and  $G$  (Plate IV. Fig. 5.) will be its directing point. But  $OG$  (Fig. 4.) is still parallel to  $AB$ , wherefore  $G$  is its vanishing point, and  $DG$  its indefinite projection, (by Theo. 3.) and  $Fa$  (in Fig. 5.) is still parallel to  $OG$ , which is the director of  $AB$ ; wherefore  $Fa$  is the indefinite projection of  $AB$  (Theo. 5.) That  $a$  found by the intersection of  $FI$  with  $DG$  (in Fig. 4.), and of  $Ed$  with  $Fa$  (in Fig. 5.), is the projection of the intersection of the original lines  $AB$  and  $AC$  (Fig. 4.), and of  $AB$  and  $AD$  (Fig. 5.) is obvious. The other construction by the lines  $AO$  is the same as by the lines  $AO$  and  $CO$  for finding the points  $a$  and  $c$ , Prob. II.

N. B. In Fig. 5. the projections  $ad$  and  $kl$  are parallel, their originals, having both of them the same director  $OH$ , according to Cor. 1. Theor. 5. The same may be observed in  $lm$  and  $cd$ , which have the same director  $OI$ .

PROBLEM.

## PROBLEM VII.

Having given the same things as in the foregoing problem, to find the projection of any figure in the original plane.

This is done by finding the projections of the several parts of the figure given, by the foregoing problem.

For example, the projection *klmnp* (Plate V. Fig. 1.) of the pentagon KLMNP is found thus. Drawing OG, OH, OI, OV, parallel to KL, LM, MN, KP respectively, the points G, H, I, and V, are vanishing points: and KL, LM, MN, being continued, cut the intersections in their intersections Q, R, T; whence drawing QG, RH, TI, are got the projections *l*, *m*, of the points L and M, by their mutual intersections. Then drawing OK and ON, are got the points *k* and *n*. Then drawing *kV* to the vanishing point V of KP, is got the indefinite projection of KP. Lastly, drawing OP is got the point *p*.

The projections of curve-lined figures are to be got by finding the projections of several of their points, and afterwards joining them neatly by hand. Thus (Plate V. Fig. 2.) DE being the intersection, and VF the vanishing line, and O the point of sight, and ABC an original circle, placed as in the foregoing problem, the projection *a* of any point A may be found by drawing at pleasure AD, and OV parallel to it; then drawing DV and OA meeting in the point sought *a*, according to the construction in Problem VI. D being the intersection, and V the vanishing point of the line AD, and the several lines AD being drawn parallel to one another, the same vanishing point V may serve for them all.

Or VF (Plate V. Fig. 3.) being the directing line brought into the picture, the rest remaining as before, drawing at pleasure AD cutting DE and VE in D and V; then drawing OV and Da parallel to it, the projection *a* is got by drawing OA cutting Da in *a*. And the same point V being used for all the points A, all the lines Da will be parallel to one another, and to the same line OV,

PROBLEM VIII.

To find the projection of any figure in a plane parallel to the picture.

The projection being similar to its original, (by Cor. 2. Theo. 4.) this is done by making an exact copy of the original figure; making the homologous sides in the proportion explained in Cor. 3. of the same Theorem.

PROBLEM IX.

Having given the vanishing line of a plane, its center and distance, and the projection of a line in that plane; to find the projection of another line in that plane, making a given angle with the former.

Let the plane HFIE (Plate V. Fig. 4.) represent the picture, which raise up and place the plane EIO parallel to the original plane HBFH. Now if we suppose O to be the point of sight, EI will represent the vanishing line. Let  $ab$  be the given projection; it is required to draw  $ac$ , so that the original of the angle  $bac$  may be equal to a given angle. Continue  $ab$  to its vanishing point G, draw GO and OI, making GOI equal to the given angle, and cutting the vanishing line in I; then draw  $Ica$ , which will be the line sought.

The reason of this construction is very easy to be understood; for the plane EOI being parallel to the original plane, it is evident that any two lines, as EO, GO, drawn from the vanishing points E, G, to the point of sight O, will form an angle at that point equal to the angle contained by those original lines, of which E and G are the vanishing points.

N. B. If it had been required to make  $abc$  to represent the angle ABC, the angle EOI must have been made equal to the complement of the angle ABC to two right angles.

PROBLEM X.

Having given the vanishing line of a plane, its center and distance, and the projection of one side of a triangle of a given species in that plane; to find the projection of the whole triangle.

The

The projections of the sides wanting are to be found by the foregoing problem, the angles of the triangle being given. Thus having given the projection  $ab$ , (see the last Figure) of the side  $AB$  of the triangle  $ABC$ , the vanishing point of the side  $ac$  is found by making the angle  $IOG$  equal to the angle  $CAB$ , and the vanishing point of the side  $bc$  is found by making the angle  $IOE$  equal to the complement of the angle  $CBA$  to two right angles.

N. B. If the vanishing point of the line given  $ab$ , is out of reach, you may proceed thus: Taking any line  $DR$ , Plate VI. Fig. 1. (parallel to the vanishing line  $HG$  by Theorem 6.) for the intersection, by means of two lines,  $HbE$ ,  $IaF$ , drawn at pleasure through  $b$  and  $a$ , find the originals  $A$  and  $B$  of the points  $a$  and  $b$ ; (by the converse of Problem I.) and draw  $AB$ . Then on the side  $AB$  complete the original triangle, and find the projection of the sides wanting by Problem VII.

#### PROBLEM XI.

Having given the vanishing line of a plane, its center and distance, and the projection of one side of any figure in that plane, to find the projection of the whole figure.

Divide the whole figure given into triangles, by means of diagonals, and find the projections of these triangles one after the other (by the last Problem), beginning with those that have the line given for one of their sides.

#### PROBLEM XII.

Having given the center and distance of the picture, and the vanishing line of a plane, to find the vanishing point of lines perpendicular to that plane.

Let  $AB$  (Plate VI. Fig. 2,) be the vanishing line given, and  $C$  the center of the picture. Draw  $CA$  perpendicular to  $AB$ , and  $CO$  parallel to it, and equal to the distance of the picture. Draw  $AO$  and  $OD$  perpendicular

dicular to it, cutting CA in D, which will be the vanishing point sought; for raise up the triangle AOD perpendicular to the plane of the scheme, (which here represents the picture) then a plane passing through the point of sight O, and the line AB will be the parallel of the original plane, and the line OD will be perpendicular to it, and consequently will be the parallel of lines perpendicular to that original plane. Wherefore D is the vanishing point of those perpendiculars, (by Def. 17.)

N. B. 1. When the vanishing line AB passes through the center of the picture, that is, when the original plane is perpendicular to the picture, the point D will be infinitely distant, the line OD being parallel to AD, and the projections of the lines perpendicular to the plane proposed, will all of them be perpendicular to AB, they being to meet the line AC, which is perpendicular to it at an infinite distance, and consequently they will be parallel to one another; which they ought to be upon another account, their originals being all parallel to the picture.

N. B. 2. But when the original plane is parallel to the picture, the distance CA will be infinite, and consequently OA will be parallel to CA, and OD will coincide with OC, making the point D to fall into the center of the picture C, agreeable to Cor. 2. Theo. 3.

N. B. 3. CD is a third proportional to AC and CO, as also is AD to AC and AO.

N. B. 4. OD is the distance of the vanishing point D.

PROBLEM XIII.

Having given the center and distance of the picture, to find the vanishing line, its center and distance, of planes that are perpendicular to those lines that have a certain vanishing point.

The solution of this problem easily follows from that of the last, for let C be the center of the picture, and D the vanishing point proposed, (see the last figure) then it is very evident that in order to determine

the point A, we must join the points D C, and draw CO perpendicular to DC, and equal to the distance of the picture; then draw DO, and make OA perpendicular to it; draw AD perpendicular to the right line DCA, and it will be the vanishing line required, A being its center, (by Theo. 1.) and OA its distance.

#### PROBLEM XIV.

Having given the center and distance of the picture, through a given point to draw the vanishing line of a plane that is perpendicular to another plane, whose vanishing line is given, and to find the center and distance of that vanishing line.

Let AB (the same Fig. as before) be the vanishing line given, and C the center of the picture, and let E be the point given. Find the vanishing point D of lines perpendicular to the original planes of AB (by Prob. XII.): Draw DE, which will be the vanishing line sought; draw CF cutting DE at right angles in F, and F will be the center of the vanishing line DE (by Theo. 1.) Make a right-angled triangle, whose base is CF, and its perpendicular is equal to the distance of the picture, and its hypotenuse will be the distance of the vanishing line DE (by the Cor. Th. 1.)

Now because the plane, whose vanishing line is sought, is perpendicular to the other plane, its vanishing line must pass through the vanishing point D of lines perpendicular to that other plane, because some of those lines are in the plane sought. Therefore DE is the vanishing line sought.

In the above construction, where DE is said to be the vanishing line sought, it is to be understood as the vanishing line of a plane perpendicular to that whose vanishing line AB is given, without having regard to its situation with respect to the picture, only that it shall be perpendicular to the plane of which AB is the vanishing line; for were the proposed  
perpendicular

perpendicular plane, when produced, to intersect the picture in a given angle, such restriction might render it impossible that the plane producing its vanishing line, should pass through both the points D, E.

COROLLARY 1.

If FC be continued till it cuts the vanishing line given in B, B will be the vanishing point of lines perpendicular to the original plane of the vanishing line DE: For that vanishing point is in the line FC, by the construction of Problem XII. and it is in the vanishing line given by what has been proved in the present Problem.

COROLLARY 2.

And therefore, if the vanishing lines AB and DE meet in G, the points B, D, and G, will be the vanishing points of the three legs of the solid angle of a cube, which are perpendicular to one another. And drawing DB, BG, GD, and DB will be the vanishing lines of the three planes that contain that solid angle.

COROLLARY 3.

The distance of the vanishing line DG is equal to the line FP, the point P being the intersection of the line FC, with a circle described on the diameter DG.

PROBLEM XV.

Having given the center and distance of the picture, and the vanishing point of the common intersection of two planes that are inclined to one another in a given angle, and the vanishing line of one of them; to find the vanishing line of the other of them.

Let C (Pl. VI. Fig. 3.) be the center of the picture, BG the given vanishing line of one of the planes, and B the vanishing point of their common intersection, and H the angle of their inclination to one another. Find the vanishing line GD, of planes perpendicular to the lines whose

vanishing point is B (by Prob. XIII.) ; let that vanishing line cut the vanishing line given in G. In GD find the vanishing point E of lines making the given angle H, with the lines whose vanishing point is G (by Prob. IX.) ; that is, in BCF perpendicular to GFD ; take FP equal to the distance of the vanishing line GD, (found by Prob. XIII.) and draw PG, and PE, making the angle EPG equal to H ; draw BE, which will be the vanishing line sought.

For a demonstration of this construction, raise up the planes EPG, BPG, until they meet in P, the point of sight perpendicular over the center of the picture C ; then if we imagine a plane to pass through P, and making the vanishing line BD, the planes BPG, GPD, DPB, will be the parallels of three original planes, whose vanishing lines are BG, GD, DB ; that whose vanishing line is DG, being perpendicular to the other two (by the construction, because it is perpendicular to their common intersection, whose vanishing point is B.) Therefore the original planes, whose vanishing lines are BG and BD, are inclined to one another in the angle EPG, or H ; (for the inclination of two planes is always measured in a plane perpendicular to their common intersection) therefore BG being the vanishing line given, BE is the vanishing line sought.

N. B. The center of the vanishing line BE is found by drawing a line perpendicular to it from C, (by Theo. 1.) and then its distance is found, as was found the distance PF in Prob. XIV.

#### OTHERWISE,

Having drawn the indefinite right line BCF, make CF equal to a third proportional to BC, and the distance of the picture ; draw DFG perpendicular to BF ; then take FP equal to the quotient arising by dividing the sum of the two squares of BC, and the distance of the picture, by the right line BF ; draw GP, and from the point P draw PE, making an

an angle GPE equal to the given angle H; which being done, draw BE, and it will be the vanishing line required.

PROBLEM XVI.

Having given the center and distance of the picture, and vanishing line of one face of any solid figure proposed, and the projection of one line in that face; to find the projection of the whole figure.

By means of the projection given, find the projection of the ichnography of the figure proposed on the plane of that face, whose vanishing line is given (by Prob. XI.); then (by Prob. XIV.) find the vanishing line of the plane of the orthography, and describe the projection of the orthography, by help of the lines already given in the ichnography (by Prob. XI.). Lastly, by the intersections of the projections of perpendiculars to the ichnography and orthography, will be found the several points of the projection required.

OTHERWISE,

Having found the projection of the face whose vanishing line is given, by means of the projection of the line given, find the vanishing lines of the adjacent faces, (by the last Problem) and describe their projections by help of the lines given in the projection of the first face, and so on, till the whole projection sought is completed.

This is a general description of the method to be used in putting any figures proposed into Perspective, and by the rules herein delivered, the following examples were actually delineated. Having in these few pages done my best endeavour to render Dr. Brook Taylor's Perspective easy to be understood, I should have here ended; but as several considerable writers upon this subject have objected against the universality of these rules, and their holding equally good, when applied to putting of some particular sorts of objects, such as round pillars, &c. into Perspective,

tive, I hope the following attempt to set this matter in a clear light, will not be disagreeable to the reader.

The appearance of an object and its representation are two very different things, the former being determined by the angle (at the eye) under which it is seen; but the latter is the actual figure formed upon the picture, by the pencil, of rays passing from every point (in view) of the object to the spectator's eye; consequently, in viewing a picture, if the eye be supposed to move about from the proper point of sight designed by the painter, it is no wonder that some remote parts in the picture should appear distorted; and for a very obvious reason, namely, because it is very possible that the representation of a right line may, upon account of its situation with regard to the picture, be much longer than the original line itself: but that a right line placed in any position whatsoever, can appear longer than itself, is absolutely impossible, and contradictory to the very nature of the science of Perspective. But to render this still plainer by an example, let AB, Pl. 39. Fig. 1. be the plane of the picture, CD an original right line, O the point of sight; draw OC, OD, and suppose CD so situated, that the angle ODC may be a right one: then it is very evident that  $Cd$  is the representation of CD; but because  $Cd$  is the hypotenuse of the right angled triangle  $CDd$ , it follows, that  $Cd$  must be longer than CD, that is, the representation is longer than the original line; but notwithstanding this, it is certain, that to the spectator's eye at O, the representation  $Cd$  can only appear as the tangent DC (OD being radius) of the angle DOC, formed by the rays OD, OC, passing from the points C, D, to the eye placed at O. For a second example of this kind, let it be required to draw the representation of a range of columns parallel to the picture. If they are drawn according to the strict rules of Perspective, then that column which is in the center of the picture will be the least, and consequently those on each side of it will be larger

larger and larger continually, the farther they are removed from the center of the picture, (if the original columns are all of the same diameter.) But to explain this more fully, let PP represent the plane of the picture, Pl. 39. Fig. 2. H, G, and I, the centers of the sections of three columns, whose representations we are to find upon the picture; and let E be the place of the spectator's eye: draw the tangent  $Eh$ ,  $Eg$ ,  $Ea$ ,  $EB$ ,  $Ei$ , and  $Ek$ ; then will their interfections with PP determine the representations  $cd$ ,  $ab$ ,  $ef$ . Now it is very evident that  $cd$  and  $ef$  are much longer than  $ab$ . From whence we may conceive, that the farther any column is removed from the center of the picture, the longer will its representation be; and we may moreover conceive, that this increase of the representations of the magnitude of the columns, is owing to the obliquity of the chords  $hg$ ,  $ik$ , with the picture; which chords will measure the apparent widths of the columns, if viewed from the proper point of sight, and will appear less and less, the farther they are removed from the perpendicular EG. But if we were to draw the appearances of these columns upon the picture, without having regard to any particular point of sight, but only that the eye be placed at a due distance from the picture; then with the perpendicular distance of the eye from the plane of the picture, describe an arch of a circle cutting the tangent  $Eh$ ,  $Eg$ ,  $Ea$ , &c. and the chords of the arches so made by these tangents, will be the apparent widths of the columns to be represented in Perspective. Thus if  $Ea = Eb$  be the radius, then will  $rs$  and  $tw$  represent the perspective appearances of the widths of the columns I and H respectively.

END of the THEORY.

## PRACTICAL PERSPECTIVE.

IN this practice of Perspective, I have thought it convenient, that the vanishing line to the *ground* plane, should be called the *horizontal* line, and the *intersection* of the *picture* with that plane, the *ground* line. In order to understand this well, I have set down the following general definitions.

### PLATE XXXVIII. FIG. I.

LH, ED, the *picture*; FM, GK, the *ground* plane.

O, the point of sight; LVH,, the *horizontal* line.

V, the *center*; the line OV, the *distance*.

CI, LH, the *horizontal* plane; CI, FM, the *directing* plane: AB, an original line; *ab* the perspective representation of it; P the intersecting point; and Z the directing point.

### CHAP. I.

Shewing in what manner any superficial figure may be put in Perspective.

The distance the spectator should stand from the *picture* (or what is meant by the point of *distance*) is very essential; for on a right choice of it depends the agreeable appearance of the objects. If it is placed very near, the representation of some objects will be greater than their originals,

originals, as *a, b*, (in Fig. 2. Plate 38.) but this must be left to the discretion of the artist, which experience will improve.

## E X A M P L E I.

PLATE VII. Fig. 1.

(Is a method made use of by an ingenious author, as the nearest distance.)

ABCD, is the *picture*, G, the *centre*, CD, the intersecting or *ground* line. Through the center, draw HL parallel to CD, for the *horizontal* line, on G raise the perpendicular GO, equal to GD, or GC, let O be the point the spectator's eye is supposed to be.

## E X A M P L E II.

PLATE VII. Fig. 2.

*To find the representation of a line given.*

The picture being prepared as above, HL, for the *horizontal* line, C, the *center*, O, the point of *sight*, DB, the *ground* line, and AB, the given line; touching the ground line in B, make OH parallel to AB, intersecting the *horizontal* line at H, for the vanishing point of AB; draw BH, and from A draw the ray OA, intersecting HB at *a*; join *aB* for the Perspective representation of the original AB.

Fig. 3.

The original AB is continued to the *ground* line at *d*, the vanishing point H, is found as in the foregoing Ex. The rays BO, AO, cutting the line *dH* in *ba*, gives *ab* for the representation of AB, and as deep in the *picture* as AB is from the ground line.

## E X A M P L E III.

PLATE VIII. Fig. 1.

In this example the *original* line DB is perpendicular to the *picture*, HL, the *horizontal* line, C, the *center*, GF, the *ground* line, and OC, the

F

*distance* ;

*distance*; continue DB to the *ground* line at *e*, and draw at pleasure two lines, B<sub>2</sub>, B<sub>1</sub>, parallel to each other, cutting GF at 1 and 2, make OE parallel to any one of them, draw 2E, 1E, then draw eC, intersecting them at *bd*, join *bd* for the representation of DB. For the line A, make OC parallel to it, then C is the vanishing point of A, and DB.

## E X A M P L E IV.

*To find the representation of a given Triangle.*

Let BAD be an original triangle, HL, the *horizontal* line, GF, the *ground* line, OC, the *distance*, produce the sides AB, BD, to the *ground* line at 1 and 2. Make OH parallel to AB, and OL parallel to BD, cutting the *horizontal* line at H and L the *vanishing* points, for AB, and BD, draw 1L, 2H, intersecting each other in *b*, draw the rays AO, DO, cutting the lines 1L, 2H, in *a*, and *d*, join *abd* for the representation of BAD. Note AD, is parallel to the *ground* line: so is *ad*.

## E X A M P L E V.

PLATE VIII. Fig. 3.

*Having an original Square given to find its Perspective Representation.*

Let LH be the *horizontal* line, GF, the *ground* line, O, the point of sight, ABDE, the original square, the sides AD, BE, being perpendicular to GF, and OC, parallel to BE, cutting the *horizontal* line at C; for the vanishing point of the sides AD, BE, and centre of the picture, continue AD, BE, till they intersect GF, at 1, and 2, draw 1C, 2C, then produce the diagonal DB, to the *ground* line at 3, and make OH parallel to DB, cutting HL, at H, H is the vanishing point of DB, draw 3H, cutting 1C, 2C, at *b*, and *d*, make *ba*, *de*, parallel to GF, (their original being so) cutting 1C, 2C, in the points *a*, *e*, join the points *abde*, for the Perspective Representation of ABDE.

EXAMPLE

## EXAMPLE VI.

PLATE VIII. Fig. 4.

*To give the representation of a square, that lies obliquely to the picture.*

Every thing being prepared as in the foregoing example, continue the sides BA, and ED, of the original square, at the ground line GF; to the points 1, 2, 3, 4, make OL parallel to AB, BL, and OH, parallel to BA, ED, draw the lines 4H, 3H, 1L, 2L, intersecting each other at the points, *a, b, c, d*, the *Perspective* of A, B, D, E.

## EXAMPLE VII.

PLATE IX. Fig. 1.

*To give the representation of a Pentagon, from an original given.*

HL, the *horizontal* line, O, the point of *sight*, GF, the *ground* line, A, B, C, D, E, the *original*, N, P, Q, M, the intersecting points on the *ground* line of the sides AB, CB, DC, EA; L, the vanishing point of the side CB, H, of the side AB, K, of the side EA, and I of the side CD. Draw PH, QL, intersecting each other at *b*, and the lines KM, IN, intersects QL, PH, in *c*, and *a*; draw the rays DO, EO, intersecting NI, MK, in *d* and *e*, join these points to finish the projection required.

Figures containing any number of sides are put in perspective in the same manner.

## EXAMPLE VIII.

PLATE IX. Fig. 2.

*To find the Perspective of a circle or any given curved line.*

HL, the *horizontal* line, EF, the *ground* line, O, the point of *sight*, and A, B, C, an *original* circle given, D its *center*. Draw at pleasure from the point B a line intersecting the *ground* line at F, and as many through the circle (parallel to BF) as you please; make OK parallel to BF, then is K, the vanishing point to them all. The point *b* of the  

F 2
original

original B is found thus, draw FK, and from B draw the ray BO, intersecting FK at *b* the point sought, the point *a* is found by drawing EK, and AO cutting EL at the point *a*, the points 1, 2, 3, and as many more are found in the same manner; the ray DO gives on the line 1K, the point *d* for the center. These points must be joined artfully for the Perspective representation.

## E X A M P L E IX.

P L A T E X. Fig. 1.

*To put an Octagon in Perspective.*

HL, the horizontal line, O, the point of sight, and GD, the ground line, AB, the original, C, the center, M, N, the intersecting points of the lines MK, IN; HL 1 2, vanishing points: viz. 1 for the side B, 2 for the side A, L, for MK, and H, of IN. Draw NH, ML, and, through their intersection, draw a line 5 6 C, and 4 3 parallel to MN; from L, through the point 3, draw a line cutting 6, 5, at 5, then draw 4L cutting 5, 6, at 6; draw 3, 1, gives 8 on ML, and 4, 2, gives 7, on NH, then a line from 2, through 3, gives *a*, on NL, and a line from 1, through 4, gives *b*, on ML, and finishes the octagon.

The circle, (Fig. 3.) is put in Perspective by the same points and manner.

## E X A M P L E X.

P L A T E XI. Fig. 3.

*To give a true Representation of a Circle in any part of the Picture, by having only a Line given as a Diameter.*

Prepare the picture in this manner. Let AB be the horizontal line, OC, the point of distance, for convenience to be transferred on the line AB, in A, and B; C, the center. Set one foot of the compasses in the point B, with the opening BO, describe the arch OL; and from AO, the arch OV; let 3, 7, be a diameter given, through the middle

dle 9, draw  $C51$ , at pleasure, from  $A$ , and  $B$ , draw lines through the point 9, at pleasure. To find the points 1, 2, 4, 5, 6, and 8; from  $B$ , through 7, draw a line, intersecting the line  $51$ , at 1; from 3 to  $B$ , gives the point 5; from  $V$ , through 7, a line drawn cuts the line  $A, 9$ , at the point 8, and from 3, to  $V$ , gives the point 4, on the same line; from  $L$ , through 3, a line cuts  $B9$  at the point 2, and another from 7, to  $L$ , gives the point 6.

This method may serve for an octagon, a square, and many other uses, and is the readiest way to represent any circles within each other.

## CHAP. II.

### Practical Perspective of Solid Bodies.

#### EXAMPLE XI.

##### PLATE XII. Fig. 1.

*To give the Representation of a Cube from an Original given.*

Let  $HL$  be the *horizontal line*,  $C$ , the *center*,  $OC$ , the *distance*, and  $H$ , *vanishing point* of  $CB$ , and  $ABCD$  the plan of the original cube, find the Perspective square,  $a, b, c, d$ , of  $ABCD$ , ~~at~~ (by Ex. V. Plate VIII. Fig. 3.) at point 2 on the ground line raise a perpendicular  $ze$  equal to any height given, on every point  $a, b, c, d$  raise perpendiculars at pleasure, from the point  $e$  of the line  $ze$ , draw a line to the center  $C$ , cutting the perpendiculars  $b, d$ , at 6 and 7, from the points 6 and 7, draw lines parallel to  $a, b$ , cutting the perpendiculars  $a$  and  $c$  at 5, 4.

#### EXAMPLE XII.

##### PLATE XII. Fig. 2.

*To find the Perspective Representation of a Pyramid, the Ichnography, or Ground Plan  $CDEF$  being given, whose Position is oblique to the Picture.*

Let  $HL$  be the *horizontal line*,  $S$  the *center*,  $O$  point of sight,

$L$

# 38 PRACTICAL PERSPECTIVE.

*L* vanishing point of the sides *CD*, *EF*, *H* vanishing point of *CE* and *FD*, the line *AB* on the ground line is a given height. Find the *Perspective* plan *edef* (by Ex. VI. Plate VIII. Fig. 4.) draw *ed*, *cf*, to find the center *a* of the *Perspective* plan, on *a* raise a perpendicular at pleasure; from *L* through the center *a* draw a line to the ground line, at that intersection set the given line *AB*, draw *BL* cutting the perpendicular *ab*, at the point *b*, join *bc*, *bd*, *be*, *bf*, and compleat your pyramid.

## E X A M P L E XIII.

PLATE XII. Fig. 3.

*To put a Cube in Perspective standing obliquely to the Picture.*

Every thing standing as in the foregoing example, the *Perspective* ground plan *abcd*, of the original *ABCD*, is found (by Ex. VI. Plate VIII. Fig. 4.) at the point *I* set a line *IF* for the given height, on every point, *a*, *b*, *c*, *d*, raise perpendiculars at pleasure, draw *FL*, cutting the perpendiculars *a*, *d*, at 5, 6, from *H*, through 5 and 6, draw lines, cutting the perpendiculars, *b*, *c*, at the points 8 and 7, then is your solid figure finished.

## E X A M P L E XIV.

PLATE XIII. Fig. 1.

*To put a Chair in Perspective from a given original Plan, whose Position is parallel to the Picture.*

Let *ML* be the *horizontal* line, *N*, the *center* and vanishing point of the sides *AC*, and *BD*, of the original plan *X*. *M*, the vanishing point of the diagonal *DA*, the small squares on the original plan are the plans of the legs; find the *Perspective* plan *a, b, c, d*, (Ex. V. Plate VIII. Fig. 3.) from the points 2, 3, on the ground line *1J*, draw *3N*, *2N*, cutting *KM*; and there determine the little square, whose parallel side is *5a*, continue a line to 6 it will give *b6*, and so finish the other squares; at *d* and

and *c*, and on every point *a* 5, 6, &c. of the Perspective plan, raise perpendiculars at pleasure. At the point 4 on the ground line *IJ*, set the perpendicular *RS*, with the heights of every member of the chair, marked *z*, *y*, *x*, *g*, 8, 7, and from every one of the points draw lines to the point *N*, cutting the line *lb*, in *l*, *u*, *v*, *t*, *e*, *f*, *b*, from *f* draw *fUT*, cutting the perpendicular *a* at *T*, draw *TN* cutting the line *ck*, at *k*, draw *bk*, parallel to *U*, *T*, then will three sides of the chair be completed; a line from *f* to *N* finishes the back. At the point *U* draw a line to the point *N* to cross the uprights, in those little lines *U* and *k*; To find the rail *s*, draw *7N*, cutting *lb* at *b*, and from *b*, draw a small line across the perpendicular on the point 6, parallel to *ba*; and from that intersection draw a line through *N*, to the leg *d*, which will give the upper side of the rail *s*; the same must be done for the other side from the line under *b*: it is easy to imagine the rails *Q*, and *P*, only they don't go across the uprights but half way, as the line *RS*, on the point 4 is in the same plane with the back of the chair. It finishes only that side, the other sides are found in the same manner as the cube, (Fig. 1. Plate XII.)

## E X A M P L E XV.

## P L A T E XIII. Fig. 2.

*To give the Representation of a square Table.*

Every thing standing as in the foregoing example, let *ABCD*, of fig. 2. be the ground plan of the table, and the little squares that of the legs; 1, 7, 6, 2, their intersecting points on the ground line. The line on the point 2, the height of the table with the parts, markt 5, 4, 3: *a*, *b*, *c*, *d*, the Perspective plan of *A*, *B*, *C*, *D*, *aq*, *pc*, the thickness of the feet, the rail *f* is carried parallel to *FJ*, cutting the perpendicular *qH*, through that intersection, and *f* draw lines to point *N* intersecting the

the back feet at  $b$ , and from thence a line parallel to  $a, c$ , through the leg  $b$ ; every line that serves to shew the thickness of the legs are contrived in that manner, G, H, E, F, represents the top.

The scheme will be sufficient without any farther explanation.

## E X A M P L E XVI.

P L A T E XI. Fig. 1.

*To give the Perspective Representation of a Cylinder, (standing perpendicular on the Ground) by only a Line given in the Picture, as the Diameter of a Circle.*

Let OH be the *horizontal* line, H, the point of *distance* laid on the horizon, O, the *center*, and V a *point to determine the circle*. Let  $ab$ , be the line, the circle  $a, B, b$ , is found, (by Ex. X. Plate XI. Fig. 3.) On the points  $a5, B6, b, i7, c8$ , and on the center, raise perpendiculars at pleasure, suppose BD, a height given, draw DO, cutting the lines,  $x, c$ , at  $e$ , and  $f$ , and through  $e$  draw a line parallel to the horizontal line cutting  $a, b$ , at  $g, h$ , from V through  $g$  draw a line, which gives the point 1, on the perpendicular line 5, and a line from  $b$  to V gives the point 3 on the line 7, from 3 draw a line parallel to  $g, h$ , it gives the point 4 on the perpendicular 8, and through 1 a line parallel to  $g, h$ , gives the point 2 on the line 6, then join those points for the circle, on the point  $i$ , raise a perpendicular to intersect the circle above at  $r$ , and at point  $s$ , erect another to give the point  $w$ , the step on which stands the cylinder is to show the perspective better. The line  $ir$  is farther from  $b$ , towards the center O, as the line  $sv$  is from  $a$ , nearer the ground line.

This representation, which is not half, is as much as we can see of a cylinder, or any round body from that point of sight.

E X A M P L E

## EXAMPLE XVII.

PLATE XI. Fig. 3.

*To shew the Perspective of a Cylindrical Body lying on the Ground at Right Angle with the Picture.*

The picture having every thing standing as in the foregoing example, the line  $aC$  vanishing at  $O$ , is the axis running through the cylinder. Every circle on the body are parallel with the *picture*, and are struck with compasses; draw  $Bb$ , to the point  $O$ . On the *ground* line  $BG$ , set the measures for the distances between the circles, and length of the body. To find the circle  $cde$ , on the line  $BG$ , let the point  $A$  be the distance for one circle: draw  $AH$ , which gives the point  $e$  on  $Bb$ ; at that point raise a perpendicular through the line  $aC$ , and  $a$  is the center for that circle. If the object should represent a cannon, as they diminish at the muzzle, let  $C$  be the small end, draw a perpendicular through  $C$ , cutting  $Bb$  in  $b$ : let 3, 4, on the line  $eC$ , be equal to the small end wanted; draw from 3 and 4 lines to  $O$ , cutting the line  $Cb$ , in 1 and 2, set one foot of the compasses in  $C$  as center, with the opening  $C1$ , or  $C2$ , describe a circle; divide your circles equally in as many parts as you please, and join them together with straight lines, as  $c2$ ,  $dR$ , &c.

## EXAMPLE XVIII.

PLATE XIV.

*To put any kind of Wheels in Perspective.*

In this example is the representation of a water-wheel, with coggs.  $HL$  the *horizontal* line,  $H$  the point of sight,  $E$  point of distance laid on the horizon,  $CM$  the *ground* line,  $VHV$  the *vanishing* line of the plane  $BEGI$ ,  $EF$  or  $5D$  the thickness; from the point 5 draw a line  $5G$  to the center  $H$ , and from  $C$  draw  $CL$ , to terminate the line  $5G$ , at  $G$ ; and from  $K$ , the center of the circle to the point  $L$ , given  $e$ , on  $BG$ , from the line  $BG$ , finish the perspective

G

square

square BGIE, draw the diagonals GE, 5I, intersecting at O, draw HO*a*, and *e o f*, then is the square prepared to draw the circles by the points VV, as has been shewn in (Plate XI. Fig. 3.) then on the point D for the thickness, draw DF, parallel to 5E, and with that line finish another square as is represented by the dotted line, and draw from each corner diagonals, as in the first square: when your first circle *ed t* is finished, set off any given height for the coggs, on 5E as 6, draw 6H, cutting *ef* in the point, to form the circle of the wheel, and so on for the next. To divide the wheel, draw a quarter of a circle as K, and divide that in as many parts as you please, it is here in 4; from every one of these points draw perpendiculars to the ground line, and from their intersection with it draw lines to the point of distance L, cutting BG, and then draw perpendiculars through one half of the perspective circle, and from those points draw lines through the center of the wheel across to find the others. For example, to find the points *b* and *f*, from B draw a perpendicular, cutting the circle in *b* and *f*, from *f* thro' the point O, draw a line cross the circle for the point *k*. For the thickness of the coggs, (supposing them in the original to diminish to the center) from the point *n* of the cogg *f*, draw a line thro' the point O across the circle, gives the point *l*. Those lines are drawn to the line VHV, and gives V, T, for vanishing points of the sides *f, n*, by this mean every circle is divided, from every point *f, n*, draw lines parallel to the horizon, intersecting the outward circle at *p*, and from the vanishing point V of *n*, draw *pV*, from *d* draw a line parallel to *n, p*, cutting *pV*, at *c*, then is *np, dc*, a compleat side of one of the coggs. To find them without using vanishing points, as it is often very troublesome to get, make the circle *c*, then from *d* the parallel line cutting that circle in *c*, join *c p*, the eight spokes are the principal lines made use here for the circle, and as it is supposed must pass through the middle of the thickness of the wheel, proceed thus, divide 5, D, in P, and a line drawn from P, to the point of distance on the line VHV, will give the line through the middle of  
the

the spoke; but to do it without that point of distance, draw the line *m* parallel to the *horizon*, divide that in two equal parts at *m*, draw *m p*, proceed for every other, join the extremity of those cross lines in a circle, to shew the inside thickness of the wheel.

## C H A P. III.

Relating to put in Perspective any Object or Objects in general.

## E X A M P L E XIX.

*How to put Doors in Perspective, and to describe Pannels thereon.*

Let Plate ~~IV~~ V. Fig. 1. represent the inside of a room, HL the horizontal line, C the center, OC the distance, V a point to find the semicircle on the floor, (described by the door opening) UR a line equal to the breadth of the door, continue U to the center C, draw a line from the point R to the point of distance (removed on the horizontal line, omitted on the plate for want of room) intersecting UC at X; let UII, be a given height, draw IIC, and on X raise a perpendicular cutting IIC, at III, then is UX, II, III, the aperture of the door; draw RC, and from X a line parallel to UR, cutting RC at T, draw XR for a diagonal, X the center, from V through T draw a line cutting XR at Y, join UYT for a quarter of a circle. The other quarter, if need be, is found, by finishing the square XTbZ, and drawing the diagonal XZ, and from C and Y draw a line cutting XZ at y; join Tyb for the other quarter; chuse any point on the semicircle for the opening, as F, draw a line from that point through X, to the horizontal line at H, for the vanishing point of lines parallel to that, and from H, through III, draw a line at pleasure, on F, raise a perpendicular cutting X, III, at a, then III a, XF represents a door opened. To form the pannels on the door, draw FE parallel to the horizon; set the foot of the compasses in H, and with the

opening HO draw the arch OL on the horizontal line, and L is the point of *distance*, and H the *vaning point* of the door; from the point L, through X, draw a line, cutting FE at E, then EF is equal to the original of FX<sub>1</sub>, set on FE, the measures 1, 2, for the width of the pannels, and from them points draw lines to the point L, cutting XF at 3, and 4, from any points on Fa. For the height, draw lines to their vanishing point H, cutting the perpendicular raised on 3, and 4, and terminating the pannels A and B.

The door, Fig. 2. at the end of the room is found in the same manner; the line KN the breadth, and KMPN a square made of that line, K is the center, or hinge of the door, with the point V on the horizon; find the point p, and finish the quarter of the circle, KW height of the door, the dotted lines from K and W vanishes to the same point on the horizon.

Fig. 3. is the representation of a trap-door on the floor. Gg the breadth, and G D 7 9, a square in perspective of the aperture, the door, D Q 6 7, is found the same as Fig. 1. or Fig. 2. KIDG is a dotted square, equal the aperture, /O the vanishing line for it, C the center, OC the distance, and the points J and L, to find the circle, then proceed as in the other Example.

### E X A M P L E XX.

#### P L A T E XVI. Fig. 1.

*How to give the Perspective Representation of Rooms, Doors, &c. The Point of Distance is set on the Horizontal Line in this and the following Examples.*

Let HL be the *horizontal line*, S the *center*, L point of *distance*, AU breadth and depth of the room, AW the height, draw AS, US, intersect US by the line AL in C, draw CB parallel to AU, then will ABCU represent the floor in perspective. To finish the sides, proceed as with a cube.

To set a door on the side of the room. On the ground line AU, let aU be the width of the door, and U b the depth it must be in the room, draw,

bL cut-

$bL$  cutting  $US$  at  $F$ , from  $F$  draw  $FE$  at pleasure parallel to  $AU$ , draw  $aS$  cutting  $FE$  at  $E$ , and the line  $EL$  will cut  $US$  at  $e$ , on  $e$  and  $F$  raise perpendiculars to make the door, the semicircle  $eEG$  and door is found as in the foregoing example,  $K$  is the vanishing point of the door  $I$ ,  $H$  the point of the door  $N$ ,  $t$  of the door  $T$ , and  $I$  of the door  $M$ . The projection of the chimney-piece is found as the door, by setting on the ground line the measures, and proceed as with the door. 1, 2, represents the back part of an upper room,  $r$  another behind it, and  $T$  the door opening within it;  $E$  the under room,  $R$  a room and pavement behind that,  $V$  vanishing point of the stairs.

## E X A M P L E XXI.

P L A T E XVI. Fig. 2.

*How to put Windows in a Room from any given Measurement.*

Let  $HL$  be the horizontal line,  $Am$  the ground line,  $L$  point of distance,  $H$  the point of sight, the points  $m, n, p, q$  the breadth of the panes and frame, and  $B, C, D$ , the height of them; lines from  $m, n$ , &c. to the point  $L$ , gives on  $AH$ , the points 1, 2, 3, 4; on these points raise perpendiculars; the perpendiculars 1, 4, gives  $aW$  on the line  $QH$ , for the square of the window-frame. To give the thickness, and represent the sides, take  $OQ$  for the thickness of the wall, draw  $OH$  from  $a$  draw a line parallel to the horizontal line, intersecting  $OH$ ; then  $k k$  is the upper thickness, and where the line  $a$  intersects  $OH$ , draw a line parallel to it;  $a1$  gives you the side: where the perpendiculars 1, 2, 3, intersect the under frame of the window, draw parallels to  $HL$ , across the window-seat, intersecting  $PH$ ; at those points raise perpendiculars for the uprights of the sashes, and from  $BCD$ , draw lines to the points  $H$  to finish the squares, continue  $aWQ$  to intersect the line  $b5$ , (at the end of the room) at 5, draw  $5l$  parallel to  $HL$ , for the top of the window; do the same to get the bottom, as is shewn by the dotted lines  $1t$ , draw  $xt$ , parallel to  $lf$ , and from  $m, n, p, q$ , draw lines to  $H$ , cutting  $b b$ , at  $e d c$ . To find

find the thickness  $g, f$ , continue  $Ok$ , to cut the line  $gb$  at  $6$ , and from that point draw a line parallel to  $lf$ , draw  $fg$  to the center  $H$ , intersecting  $6g$  at  $g$ , from that point draw a line parallel to  $f, e$ , for one side of the window; and draw  $zh$ , intersecting that line; from that intersection draw a line parallel to  $xz$ , for the thickness of the bottom. The cross bars are found by drawing lines from the points  $7, 8, 9$ , to  $W$ , and from their intersections on the line  $g$ , draw lines parallel to  $xz$ .

## E X A M P L E XXII.

P L A T E XVII. Fig. 2.

*To put a Tuscan Pedestal in Perspective.*

On the ground line  $AK$ , raise a perpendicular  $ac$ , for the height of the members, as  $1, 2, 3, 4$   $bc$ , for the projection of those members take  $4e, 3d$ , &c. On any point of the ground line, raise the perpendicular  $AC$ ; on it set the points  $1, 2, 3, 4$   $BC$ , equal to those in  $ac$ , as  $Ai$  the height of the plinth, &c. At  $i$  draw  $GF$  parallel to  $AK$ ,  $iG$  or  $iF$  is equal to half the width of the plinth, from  $G$  and  $F$  draw lines to the center  $H$ . On the ground line set the depth (equal to the line  $GF$ ) from  $G$  to  $K$ , draw  $K$  to the point of distance  $I$ , cutting  $GH$ , at the point  $l$ , raise a perpendicular, and finish the plinth; from each corner draw the diagonals,  $Fb, GL$ , intersecting each other in  $O$ , the center of that square; set the different projections from the line  $a$  to  $d$ , and put them on from  $i$  towards  $D$ , draw  $iH$ , and from the first point on  $iD$  draw a line to  $I$  intersecting  $iH$ , at the intersecting point draw a line parallel to  $GF$ , cutting the diagonals  $GF$ , and from those intersections draw lines to the point  $H$ , intersecting the diagonal at  $b$ , on each point raise perpendiculars, for the height of the fillet, then from the point  $2$ , the height, draw a line  $2H$ , cutting the perpendicular on the line  $iH$ , for its proper height; from that intersection draw a line parallel to  $GF$ , intersecting that perpendicular, and then on the diagonals  $GF$ , and finish the fillet in the same

same manner as the plinth; the other members are laid on in the same manner. For the capital of the pedestal, proceed as for the base. As the flat band BC projects flush with the plinth, from B to E lay the profile of the members, draw BH, intersect it by EL, and finish every member before you lay another on it.

## E X A M P L E XXIII.

P L A T E XVIII. Fig. 2.

*How to lay Members of Architecture on one another.*

Let ABCD be a square plan in Perspective, where on it another is to be put on equally every way, GP *horizontal line*, G *center*, P *distance*,  $rx$  is the *distance* it is to be laid on; draw the diagonals AC, BD, where  $rP$  intersects  $xG$ , draw the line  $ad$  parallel to AD, cutting the diagonals at  $a$  and  $d$ , from those points draw lines to G, cutting the diagonals B and C at the points  $b$  and  $c$ , then will the plan  $abcd$  be placed equally on ABCD.

## E X A M P L E XXIV.

P L A T E XVII. Fig. 1.

*In this Example is the Perspective of the Tuscan Entablature.*

Let X represent the original, on the line AD are set the height of the parts, viz. 1, 2, 3, 4, &c. and from those as AB,  $1b$ ,  $2c$ ,  $3e$ , &c. are the distances they are from that line, (this figure is put on the plate upside down for want of room) LH, the *horizontal line*, H the point of sight, and L the point of *distance*, laid on the horizontal line. Let FE be equal to the whole width of that member, divide it into two equal parts at  $a$ , let fall the perpendicular  $ad$ ; on that line set the measures from AD, 1, 2, 3, &c. on  $aF$  set their projections from the line AD, as  $b$ ,  $e$ ,  $f$ ,  $g$ , &c. with the line FE make a perspective square plan, draw diagonals across, from  $a$  draw a line to H, from  $b$  draw  $bL$  cutting  $aH$  at  $n$ , through  $n$  draw a line parallel to FE cutting the diagonals at MM, draw MH till it cuts the diagonal;

on  $nMM$  raise perpendiculars. From the point  $i$  on  $ad$  draw a line to  $H$ , cutting the perpendicular  $n$ , and from that point draw a line parallel to  $FE$ , cutting the perpendicular  $MM$ , and finish that member as if it was a plinth; then on the corners at  $F$  and  $E$  draw the quarter round, and proceed the same for the rest, observing that every member lies properly on the diagonal of the preceding.

### E X A M P L E XXV.

*In this Example is the Perspective of the Tuscan Base.*

Let  $X$  in Plate XVIII. Fig. 1. be an original section made as in Plate XVII. Fig. 1. But to give the proper representation of the swell of the Torus, I have divided the original in two equal parts, horizontally as marked 2, and vertically marked  $x$ ; and where the line  $x$  cuts the Torus, lines are drawn parallel to  $xa$  against  $a5$ , in the points 1 and 3, to express the swell. The base is supposed parallel with the picture, and the plinth  $BD$ , whose height is  $AP$ , is put in Perspective in the same manner as a square;  $SL$  the horizontal line,  $S$  the point of sight, and  $L$  for the distance; on the surface of the plinth, draw diagonals. Their intersection  $o$  is the center of the base, through that point  $o$  draw a line parallel to  $DB$ , for a diameter, and from the  $S$  through  $o$  draw a line for the other, and given the point  $A$  on  $BD$ , with the point  $V$  make the circles on the plinth, as has been shewn in Plate XI. Fig. 3. On  $A5$  set the height of every member, as 1, 2, 3, &c. on  $AJ$  are the measures for their projections. The point  $c$ , for one perspective circle, is found by the line  $JL$ , cutting  $AS$  in that point; the other points on that line are found in the same manner: those points are afterwards carried on one of the semi-diameters, by continuing a line from those points to the point of distance intersecting the semi-diameter, then with a pair of compasses carry them over to the other, as  $abc$ , then from  $V$  and those points finish your circles, on the center  $o$  raise the perpendicular  $Ko$ , and through every point 1, 2, 3, &c.

&c. on the line A5, draw lines to the point S, cutting K0 in 1, 2, 3, &c. On that part of the circle you intend for a section, draw a line through the center K0, to the horizontal line; and the intersection will be the vanishing point, from that point draw lines through every point on K0, cutting the perpendiculars on the points for the circle of that section. For Example: Suppose for the section on the line AH, S is the *vanishing point* for it, on every point *abc*, on AS raise perpendiculars, and from S through every division on K0 draw lines, cutting them. The first point on A marked 2, for the middle or greatest swell of the Torus; on the second, in two places to express the turning of the round; on the third, at *b* 4 and 5, the point *b* joining the plinth, and 4 where the fillet begins, 4 and 5 the height of the fillet, on *c* at *d* the shaft begins, do the same on as many parts of the circle as you think necessary to compleat your figure. Then join artfully the points 4 4, 3 3, 2 2, &c. in curves. R is part of a section behind that on the diagonal B, *a* is part of another; to finish this figure to a great nicety, girt the sections with as many of those curves as will fill the spaces.

When the learner has accustomed himself in viewing a true representation, he may with only the circles compleat the Torus.

## E X A M P L E XXVI.

P L A T E XVIII. Fig. 3.

*In this Example is the Perspective of the Tuscan Capital.*

The line AJD is made use as a *ground line*, HL the *horizontal line*, L the *center* of the picture, H point of *distance*, and V one point for the circle, CD the width of the abacus, J the middle of it, *abdg* the projection laid on from J towards D, Jr a line for the height of the parts, as 1, 2, 3 &c. KO the center of the column, ABDC an original section; proceed with this exactly as with the foregoing Example.

H

EXAMPLE

## EXAMPLE XXVII.

PLATE XIX. Fig. 3.

*In this Example is the Perspective of a double Cross.*

Let LH be the *horizontal* line, AD the *ground* line, L the *center*, H the point of *distance*, ABCD the extent of the cross bar, BC the thickness; draw AL, BL, CL, DL, and from A draw AH, gives the points *b c E*; through these points draw lines parallel to AD for *ag* on AL, and *d* on DL; on the point B set the perpendicular BG, with the height of the parts required; then on the points *b c e f*, plan of the upright post, raise perpendiculars at pleasure, and through the points on BG, draw GL, KL, IL, cutting *bo* at *qr*, draw through the point *r* a line parallel to the ground line, cross the perpendicular lines *cb* as *m r s t*, and another parallel to it through *q*; IK, Kn, is the end of one of the cross bars, draw KL and IL; perpendiculars on *ag dF* will terminate the points *mQt*, &c. where the line IQ intersects *fp*, draw a line parallel to *mt*, from *tm* draw lines to the point L, a perpendicular on *g* will finish the side *mL*.

Plate XIX. Fig. 2. is the representation of a bureau with the flap open. *b, i, k*, is the circle described by the flap opening, PL the *horizontal* line, L the *center*, O, O, X, the *vanishing* line to BA*i*, O O two points to contrive the circle, X the point of distance on OLX, A*k*M the flap, A the point it turns on; proceed in this as in Plate XV.

## EXAMPLE XXVIII.

PLATE XIX. Fig. 1.

*To find the Middle or Center of any Building, &c.*

Let HV be the *horizontal* line, V the *center*, H the point of *distance*, and EC one side of the building, through E draw HA, to the ground line AG, divide AC in two equal parts at F, draw FH, cutting CE at D (the middle of EC) raise the perpendicular DL, cutting RK at L, draw a line parallel to

AG, intersecting MV, divide that line in the middle, and describe the semicircle LQ from V, and through the center of that semicircle draw a line, it will give the point Q on it, which is the center of the arch MNR, as required.

## E X A M P L E XXIX.

## P L A T E XX.

In this example the eye is so placed in the air as to look down in the building, VUB and RUS are two *vanishing* lines at right angle, U is the *center* of the picture, R and S two points of *distance*; the line GI parallel to RS, for convenience, must be conceived as a *ground* line, ABCD an original arch given, PG is equal the line BC, PA the thickness of the pilaster, PI is half the breadth, and NO the extent of the capital and base; intersect PU by GR, to get the point g; LM drawn to R, gives on PU, *b, l, m*, the same parts of the original, as by their capitals; from them, lines are drawn parallel to GI, IU terminating the side *a*, NU gives *nn* for the projection of the base and capital. To turn the perspective arch, W on the ground line being for its center, draw WU cutting *tt* at *x*; from R and S through *x*, draw lines at pleasure, for diagonals *xv, xy*. To turn the arch, draw *Ztv, Zty, Stp*; join *t, y, p, v, t*. The sides of these pilasters are parallel to VUB; the window 1 2, 3 4 is found by drawing 2U, 5U; for the thickness, draw 1U, and draw 4 3 parallel to RS, cutting 1U at 3, and from 3 draw a line parallel to VB; finishing the bottom of the window, if any depth for the window is required, set them on the front line, draw SU, and intersect that line, by another from a given point, to a point of distance, as sT draw *st* parallel to VB, then that is the side of a square; and if from *t* you draw another to the point of distance, cutting SU, the window will be double its breadth: In this scheme the pavement being parallel to the *picture*, every square remains the same. To find the point of distance T, the line VB, and Ts their intersection is the point required. Cielings are represented in the same manner. These arches need only be inverted.

## CHAP. IV.

To represent inclined Planes and Objects.

## EXAMPLE XXX.

PLATE XXI. Fig. 1.

*To represent an inclined Plane, whose inclination is given, having one side parallel to it.*

Let HL be the *horizontal* line, S the *center*, or point of sight, L the point of *distance*; draw SO perpendicular to HL, draw LO parallel to Y the inclined surface, cutting SO at O, for the *vanishing* point of that plane; through that point, draw VU parallel to HL; set one foot of the compasses at O, and the other in the point of distance L, draw the arch LV; then V is the point of distance to it. When the picture is thus prepared; set GB as one side, on the ground line GF, draw GO, BO, and from V, draw GV, cutting BO at I, draw IK parallel to GB; for the bottom that lies flat on the ground, draw BS; then finish it by the perpendicular *ia*. The square *de*, *fg*, Fig. 2. is found the same; *de* being given.

## EXAMPLE XXXI.

PLATE XXI. Fig. 3.

*In this Scheme is the Perspective of a Prism that has one Side perpendicular to the Ground, and resteth on an inclined Plane.*

Let HL be the horizontal line, S the center, and the point L the distance, Z the original prism, X the inclined plane, draw SO perpendicular to HL; set the prism Z at the point of distance L, and draw LO parallel to the upper surface, and LV for the under, cutting VSO at O and V; through these points draw lines parallel to HS, and from V and O, with the distance L describe the arcs KL, LN; the surface of the wedge being parallel with the upper surface

surface of the prism, the point O is the vanishing point to both, and V vanishing point to the under side of the prism; for the perspective of the plane X, proceed as in the foregoing example, Fig. 1. Let  $nl$  on the perspective plane X be given (parallel to HL) through  $nL$ , from V draw lines at pleasure, from N point of distance through  $l$  draw a line cutting  $na$  at  $a$ , make  $ab$  parallel to  $nl$ , from  $a$  and  $b$  draw  $aO$ ,  $bO$  either draw a perpendicular on  $l$  to find the point  $ld$ , or the line  $Ka$ , make  $de$  parallel  $ab$ . Fig. 4. is the ground plan of a square (whose position is oblique to the picture) on an inclined plane,  $bd$  a line given. From I and K the two points of distance, draw lines through  $b$  and  $d$ , intersecting each other at  $a$  and  $c$ .

## E X A M P L E XXXII.

## P L A T E XXII.

*In this Example are Stairs put in Perspective, standing parallel with the Perspective.*

Make NL the *horizontal* line, S the *center*, N the *distance*, I the given inclination, V the vanishing point of the inclination found, as by (Ex. XXX. Plate XXI.) Let 3 4 on the ground line be the depth, and FE the height of a step; draw FS, ES and 3N, 4N cutting ES at 2 and 1, there raise perpendiculars cutting FS at 5W for the first step of the flight K, then draw 5V, WV, the point  $d$  is found by drawing a perpendicular from W, intersecting 5V at  $d$ , then draw  $dS$  intersecting WV, and so on for as many steps as you please. The rails of the flight C vanishes at V, and the top of the landing place at S; and every steps having their sides perpendicular to the picture, the points  $kqp$ , &c. are found as the point  $d$ , the stairs N that runs below, are found by drawing a line from V through Y, and proceed as with the first step K. X a ray of light, and parallel to the picture, 6 6  $r r$  shadow of the rail D on the stairs.

## EXAMPLE

## EXAMPLE XXXIII.

PLATE XXIII. Fig. 1.

*In this Example is an inclined Chair in Perspective, and parallel with the Picture.*

Let SQ be an *horizontal* line, CD a *ground* line; make USN perpendicular to SQ, S the *center*, Q the *distance*, QU a vanishing line for the side KA, or inclination above the horizon, NU the vanishing points, QN the vanishing line for the side DA, CB, &c. or inclination below the horizon; through the points N and U, draw lines perpendicular to NSU; on them set P and R as points of distance, P equal to NO, and R equal UO, on C2; 1D thickness of the legs; for the plane ABCD draw NCB, NDA, then from P draw a line through D, cutting BC at B, make BA parallel to CD; for the side BLKA, being a square, draw BU, AU and BR intersecting AU at K, draw KL parallel to AB. For the side ML, CB, draw CU and LN cutting CU at M; the rail *b*g is parallel to CD, and the sides vanishes at N. The diagonals FG, JP, intersects at O, for one of the rails FP, another &c. The length of this chair is known by the number of diagonals, every two diagonals forming a square, whose side is equal to BA. Fig. 2. is a chair finished.

## EXAMPLE XXXIV.

PLATE XXIV. Fig. 1.

*To put an inclined Cube in Perspective, whose Position is oblique in the Picture.*

Let HL be the *horizontal* line, S the *center*, the perpendicular, SO the *distance*, and *ac* a given side of a cube in the picture: continue *ac* to the horizontal line at H, draw HO and LO perpendicular to it; then H and L are two vanishing points. L for *de*, H for *bd*, *ac*, *fg*, through L draw CLA perpendicular to HL; then with one foot of the compasses in the point L, and with the opening LO, describe the arch OC; make AL equal LO, C is the vanishing point of *df*, *ac*, *bg*, and A of the sides *ad*, *ef*, *cb*; draw

HA

HA, vanishing line for the side  $ac$ ,  $bd$ , &c. draw SB perpendicular to AH. To find the point of distance E of that line, divide HA in two equal parts at G; set one foot of the compasses in G, with the opening GH describe the semicircle HEA; through B draw a perpendicular line to HA, cutting the semicircle at E; join AE, HE, which is a right angle, as the original. Through the given line  $ac$ , draw  $Aad$ ,  $Ac b$ , at pleasure; at the point E set off  $45^\circ$ , (that being the angle, the diagonal makes with the side of a square;) at  $b$  and through  $b$ , draw  $EbD$ , from D through  $c$ , draw a line cutting  $ad$  at  $d$ , and draw  $dH$ , intersecting  $cb$  at  $b$ , draw  $dC$ ,  $bC$ ,  $aC$ , and  $dL$  as a diagonal, cutting  $aC$  at  $e$ , draw  $Ae$  at pleasure, cutting  $dC$  at  $f$ , and draw  $fH$ , intersecting  $bC$  at  $g$ , and the cube is finished. If the diagonal  $dg$  is required, find  $k$  on CH, as the point D on AH.

## E X A M P L E XXXV.

P L A T E XXV. Fig. I.

*In this Example in an inclined Chair in Perspective.*

Every line points, &c. standing as in the foregoing; the diagonals are got by E, D and L;  $ab$ ,  $cd$ ,  $efg$ , are found as the cube; the back of the chair is three times its width, as appears by the diagonals  $dgi$  and  $k$ , which are drawn to the point E.

## C H A P. V.

Of finding the Shadows of given Figures.

Shadows are only the projections of given figures on given surfaces, by means of given luminous bodies; but to avoid the difficulties that would attend the description of shadows, if the magnitude of the luminous body were taken in consideration, it being sufficient for practice to regard only the center of it; therefore in these examples, a luminous body will be considered as a point.

EXAMPLE

## EXAMPLE XXXVI.

PLATE XXV Fig. 1.

Let HL be the horizontal line, C the center, and R ray of light, supposed to come from the sun, and parallel to the picture; from every corner of the Fig. A at top, draw lines parallel to R, as 1 4, 2 3, and from their seats *a* and *b* draw lines parallel to the ground line, intersecting them at 4 and 3, or else find only the point 4, as C is the vanishing point of the side *ab*, 1 2, draw 4C, and at *b* draw a line parallel to the ground line, cutting 4C at 3.

The shadow *feg* of the prism B is found in this manner, L is the vanishing point of the side *cde*, make *f* parallel to the ray R; from the seat of *c* at *a*, draw a line parallel HL, intersecting *cf* at *f*, draw *fL*, and from *g* the seat of *d*, draw a line parallel to *af*, cutting *fL* at *e*.

To find the points *bcd* of the shadow of the inclined cross D, from C through 4, draw a line at pleasure; at 2 draw a line parallel to 1 4, cutting 4C at *a*, the seat of 2, from the point 2 make a line parallel to R, and from the seat *a* a line parallel to HL, cutting it at *b*; the point *c* is found by drawing 1c parallel to 2*b* or R, and 4c parallel to *ab*, the point *d* is found the same.

## EXAMPLE XXXVII.

PLATE XXV. Fig. 2.

*In this Example the Light comes from behind the Picture.*

HL the horizontal line, O the center, on HL at H raise the perpendicular RH, R is the vanishing point of the rays of the sun, and H is the vanishing point of the shadow on the ground; to find the points A, B, C, shadow of the solid figure D, draw a line for R, through the point 1, at pleasure, and through *a* (the seat of 1) and H draw a line intersecting R1 at A, the point B and C are found the same. Observe as O is the vanishing point of the side, 2 3, it is also of the shadow BC, the shadow of the cross is found in the same manner; and the shadow of it over the block S is found, by continuing that

of

of the body of the cross on the ground, till it intersects the side  $r$  of the block, and from that intersection, draw a line parallel to the upright of the cross, till it comes to the surface at  $t$ ; and from that point and  $H$ , draw the shadow over it, (as it runs parallel with that on the ground) every point is found as in Fig. D. The shadow of the cylinder is found by setting off as many points on it at pleasure as  $a, b, c$ , find their seats on the ground as  $5, 6$ , &c. then proceed the same as with the solid figure D,  $5$  is the seat of  $c$ , and  $1$  is the point of shadow, &c. Note, when the sun is supposed behind the picture, the vanishing point of light is above the horizon.

## E X A M P L E XXXVIII.

P L A T E XXV. Fig. 3.

*In this Scheme the Light from the Sun is before the Picture.*

HV the horizontal line, C the center, V the vanishing point of the shadow on the ground plane, L the vanishing point of light coming before the picture; the point 3 the shadow on the ground of point  $b$  of the stairs, is found by drawing a line through its seat  $a$  to V, and another from  $b$  to point L, intersecting  $aV$  at 3 the point sought. The points 1, 2, are found the same,  $b, g$  vanishes at C, as does the shadow 3 4. The shadow on the step 3  $bc$  is, by drawing 3 V, the shadow of the stick A on the stairs is projected by drawing AV, till it meets the bottom of the stairs; make the shadow  $e$  parallel to the stick where it meets the top, continue it towards V, the dotted lines from the head of the stick to point L, terminates the shadow of it on the flat top of the steps. The dotted lines of Fig. K, sufficiently explain it, the side  $ed$  is parallel to the horizon, so is its shadow.

N. B. When the light is before the picture, the vanishing point of light is below the horizontal line.

## E X A M P L E XXXIX.

P L A T E XXVI. Fig. 1.

*In this Example the Light is supposed before the Picture.*

V is the vanishing point of shadow, W the vanishing point of rays of light, at any point on the quarter round where you want to project a shadow, make the section as by Example XXV. The point 4, shadow of *b*, is found by drawing *bV* cutting the quarter round at 3, there make a section, draw *bW* intersecting that section at point 4, point 2, shadow of *a* is found the same.

## E X A M P L E XL.

P L A T E XXVI. Fig. 2.

X, S is the horizontal line, X the center, S the vanishing point of the shadow on the ground, R that of light, come before the picture, CAB is a square board placed on the top of a cylinder, *abc* the seat of A, B, C, on the ground, and 1, 2, 3, 4 its shadow. The point J, the shadow of A on the cylinder is found by drawing A, S, cutting the top of the circumference, and from that point let fall a perpendicular, draw AR, intersecting it at J, the point sought; set on as many points on ABC, as may serve to complete the shadow, and proceed with every one in the same manner. E is the shadow of *e*, and *d* its seat on the ground, draw *dS* intersecting the bottom of the cylinder at D, there raise the perpendicular DF at pleasure, draw *eR* cutting it at E, the line *dDE* is the shadow of the rail *de*, and the points G, F, &c. are found as point E. The scheme is sufficient to explain the rest, the lines projecting the shadows being on the plate.

## E X A M P L E XLI.

P L A T E XXVI. Fig. 3.

In this scheme C is the center of the picture, H the vanishing point of shadow on the ground, and L the vanishing point of rays of light. To find the

the points  $q$ ,  $S$ ,  $y$  shadow of  $K$  on the cylinder, from any point  $2$  on the circumference of the base of the cylinder (which is parallel to the picture) draw  $2C$ , and from its seat  $g$  draw  $gC$ ; then from the seat of  $K$  draw lines to  $H$  cutting  $gC$  in  $f$  and  $u$ , make  $fy$ ,  $uy$  perpendicular to the ground line, cutting  $2C$  at  $q$ , and  $y$  the points sought; to find  $S$  take any point  $r$ , and proceed as with point  $Q$ ; any points  $n$ ,  $m$ , of the shadow of the circumference of the inward cylinder on its surface, are found thus; draw  $CL$ , and  $at$ ,  $bl$ , parallel to it, cutting that circumference in  $at$ ,  $bl$ , then drawing  $aS$ , and  $tC$ , meeting in  $n$ , and  $bS$ ,  $lC$  meeting in  $m$ ,  $n$ ,  $m$ , are the points sought,  $b$  being the seat of the point  $s$  on the outward circumference, draw  $lL$ ,  $bH$ , and their intersection is the shadow of point  $l$ . Fig. 4. is a hollow cylinder cut open, every thing else standing as in the foregoing example,  $ar$ ,  $bs$ ,  $ct$ , are parallel to  $CL$ , draw  $rC$ ,  $sC$ ,  $tC$ , and  $aL$ ,  $bL$ ,  $cL$ , intersecting each other at  $e$ ,  $d$ ,  $f$ , shadow of  $abc$ ,  $5$  is the seat of point  $3$ , by drawing  $3L$  and  $5H$  intersecting it at  $2$ , give  $2$  for the shadow of point  $3$  on the ground.

## E X A M P L E XLII.

## P L A T E XIX. Fig. 1.

In this scheme  $VH$  is the horizontal line,  $V$  the center; make  $RS$  perpendicular to  $VH$ ,  $S$  the vanishing point of shadow on the ground,  $R$  the vanishing point of rays of light. Then in the circumference of the arch  $ONB$  (which is parallel to the picture and vanishing at  $V$ ) taking any point  $O$ , and finding its seat  $A$  on the ground, draw  $OR$ ,  $AS$ , intersecting at  $o$  the point sought; the point  $n$  on the wall  $E, K, B, C$ , shadow of  $N$ , is found by drawing through  $P$  (the seat of  $N$  on the ground)  $PS$  cutting  $EC$ , (the seat of the wall) in  $p$ , draw  $NR$ , and  $pn$  parallel to  $DL$  or  $EK$ , intersecting  $NR$  at  $n$ . In the same manner are got all the points that form the shadow of the arch; look for point  $R$  at the bottom of the plate. The points  $d$  &  $f$  in Fig 2. are found in the same manner as point  $n$  in the foregoing example;  $A$  is the

original point, B its seat on the ground, W the vanishing point of shadows on the ground, and A on the ground line; BD the vanishing point of rays of light, *c* the intersection, and *d* the shadow of A.

## E X A M P L E XLIII.

PLATE XXVII. Fig. 3.

In this scheme the light is from the candle L, and L is the point of light, K its seat on the ground, and C the center of the picture; from K draw a line parallel to the ground line, cutting the seat of the side of the room TPX at T, draw TP parallel to KL, and LP parallel to KT, cutting TP at P, seat of light on that side the room, produce TP to X; make LV parallel to PX and XV, parallel to LP; point V is the seat of light on the cieling; W is the seat of light on the farther end of the room, and is found by drawing CK, where it cuts the intersection of that side of the room and the floor, raise a perpendicular, and draw CL, intersecting it at W. Having the different seats of light, proceed in projecting the shadows which are found in the same manner as from the sun. Point *b* shadow of *d*, is found by drawing through K, and the leg of the table, a line at pleasure, intersecting it by L*b* at *b*, and every point of shadow on the ground of the table is found the same way; point *p* shadow of *y*, is found by drawing L*p* at pleasure, and through the seat of *y* and P, draw a line cutting L*p* at *p*, in this manner you may finish the shadow on the wall, of the circle I *y*. To find point 8 on the side of the room, thro' K and 4, draw a line cutting the seat of that side of the room at *t*, and draw a line through L and the top of the chair at pleasure, then draw 7 8 perpendicular to the ground line intersecting at 8. The points *i*, *b*, *k*, on the cieling, shadow of the cross *e*, *g*, *f*, are found by drawing through the seat of *e*, *g*, *f*, and W, lines cutting the intersection of the cieling at *n*, (the cross being perpendicular to the picture, its vanishing point is C) then through *n* draw C*n**b*, and through every intersection for the points *i*, *k*. The shadow of the ball on the

the cieling is better understood by Fig. 3.  $l$  is the point of light, and  $S$  its seat,  $C$  the center of the ball, draw  $Cl$ , divide it in two equal parts in  $k$ ; set on the foot of the compasses in  $k$ , with the opening  $kC$ , cut the circumference of the ball in  $E$  and  $F$ , draw the line  $ExF$ . On the diameter  $3C4$ , make the circle  $1234$ , parallel to the ground plane, and make another passing thro' the points  $1, 2$ , and the line  $Ck$ ; thro' the points  $x$  and  $V$ , draw a line cutting the circle  $2651$ ; at  $5$  and  $6$ , and make the circle  $E65F$ . That upper part of the ball is as much as can be enlightened by a light placed at  $l$ , or as much as can be seen by a spectator at that distance. Find the points  $e65f$ , seats of  $E, 6, F, 5$ ; then from  $S$  the seat of light, and through  $e56f$ , &c. draw lines parallel to the horizon, intersecting them by lines thro'  $l$  and the points  $E6, F5$ , at  $n, r, m, s$ , join those points for the shadow of the ball on the ground.

## E X A M P L E XIV.

Fig. 2. In this scheme  $R$  is a ray of light from the sun parallel to the picture,  $V$  the center of the picture,  $1645$  a section parallel to the ground plane,  $1234$  another perpendicular to the line  $R$  (as the rays from the sun are to be considered as parallel, one half of the ball is enlightened.) The shadow of  $pnl$  on the ground is found by drawing thro' every point of the circle  $1234$  lines parallel to  $R1$ , as  $V3, P9$ , and lines parallel to the horizon, passing thro' their seats, intersecting them at  $pnl$ , the little circle on the ground is the seat of the great one  $1234$ , and is marked by the same figures.

Of finding the Reflection of any Figure on polished Planes or Standing Water.

## E X A M P L E XLIV.

## P L A T E XLV.

It is well known, that the reflection of figures on a polished plane, or on the surface of standing water, appear to be just as much on one side of the plane, as the real objects are on the other side: so that to find the reflected representation of any point, you must draw a perpendicular to the reflecting plane from the real point, and in it take a point at the same distance on the contrary side of the plane. For instance, to find the reflection of the perpendicular AB (Plate XXXVII.) let AC be the surface of the reflecting plane, and A the seat of B, continue the perpendicular AB downwards, till Ab is equal to AB. The angle any original line makes with the reflecting plane, is the same as the reflection with that plane.

As in F (Fig. 2.) DC the surface of the water, the angle CDF is equal to the angle CDf of the reflection. Vanishing points of any real objects are the vanishing points of their reflections, as O, Fig. 3. is the vanishing point of the square board, and its reflections: the construction of that figure is sufficiently clear by the scheme only.

## E X A M P L E XLV.

## P L A T E XXVI. Fig. 3.

In this example the surface of the water is supposed even with the ground, or the line *bg*, and the circles in the reflection are the same size as the real ones, and the same distance from the line *bg* downwards, C is the vanishing point, and every point of shadow in the reflection may be found in

in the same manner, as  $nm$  in the real figure, making  $LH$  equal to  $HL$ , and using the point  $L$  instead of  $L$ .

## C H A P. VII.

## Of the Perspective of Landscapes.

## E X A M P L E XLVI.

## P L A T E XXVIII. Fig. 1.

In this example is represented a landscape that has a descent marked  $GabI$ , a rising ground  $e d K n$ , and  $GC$  a flat country,  $HL$  the horizontal line,  $C$  the center, and  $L$  the distance,  $BF$  the vanishing line of a plane inclined below the horizon,  $LB$  its inclination,  $B$  the center, and  $F$  the distance on it,  $AS$  the vanishing line of a plane inclined above the horizon,  $LA$  its inclination,  $A$  the center,  $S$  the point of distance on it; draw  $GB$ ,  $IB$ , and  $GF$ , cutting  $IB$  in  $b$ , make  $ba$  parallel to  $GI$ . For the square piece of water, draw  $aC$ ,  $bC$ ; then  $aL$ , or  $bH$ , cutting  $aC$  at  $c$ , make  $cd$  parallel to  $ab$ . For the ascent, draw  $cA$ ,  $dA$ , intersecting  $cA$  by  $dS$ , at  $K$ , make  $Kn$  parallel to  $cd$ .  $GKnI$  being perpendicular to the picture, vanishes at  $C$ , and  $D$  is the vanishing point of the house  $E$ . To find point  $k$  in the water ( $ao$  being the surface) draw the perpendicular  $Kk$  at pleasure, and  $aC$  cutting it at  $r$  ( $r$  is the seat of  $K$  on the water) make  $rk$  equal to  $rK$ , the points are found the same,  $ck$  is the reflection of  $cK$ , and  $ks$  of  $Kn$ .

The shadows which are supposed to be cast by the sun, and parallel to the picture, the line  $R$  the inclination of the rays of light, make  $li$  parallel to it, and  $bI$  parallel to the horizontal line, join  $Ii$ . For the shadow of  $I$  on the slope, draw  $im$  to the point  $C$ , cutting  $cd$  in  $m$ , join  $nm$ , then  $Iimn$  is the shadow of  $I$  on the down-hill surface of the water and rising ground. The posts  $T$ ,  $U$ , and their shadows, vanish at  $B$ . Plate XXIX. will sufficiently explain the rest.

## EXAMPLE XLVII.

## PLATE XXVIII. Fig. 2.

In this example HL is the horizontal line, C the center (or the point of sight removed in the picture) GD the ground-line, B a rising ground, ND the seat of it, NB the perpendicular height at B, equal to DA on the ground-line, KNI being produced towards the horizontal line till it cuts it, that point is the distance; and if KN, GD, be continued till they meet, from their intersection to D will be the real distance between the point D and point N. The level ground at a great distance rises to the horizontal line; the tops of the hills higher, but their seats are below it. The light which is from the sun is parallel to the picture, and the line R the inclination of the rays of light, every shadow, and reflection in the water is found as in the foregoing example. Plate XXX. represents the same finished.

## EXAMPLE XLVIII.

## PLATE XXXI.

In this landscape are represented several streets, whose vanishing points are H, C, L placed on the horizontal line HL, C is the center of the picture; the houses standing obliquely with the picture, have one side vanishing at point L, the other at H; the house F having one side perpendicular to the picture vanishes at C; the streets are supposed to be at right angle with each other; O an octagon basin, the perspective of it is found by the points H, *d*, *e*, L on the horizontal line, and *lm* as diameter. On VH, perpendicular to HL, are set the vanishing points Q S. The side of the roofs vanishes at S, the shed C at Q, and the roof *v* of the house *e* at V; the opposite side forming the angle vanishes at a point as far below the horizontal line as the other is above it. Make *kC* perpendicular to HL, continue one side of the pediment *g* of the house F, cutting *kC* at *k*, the vanishing point for that side. If lines are drawn from the top and bottom of the house *e* to the point L, any line perpendicular to HL between those lines, as

1, 2, will be equal to the height of the house *e*. Thro' 1 and 2 draw lines to H, for the top and bottom of the houses in that street, the line RL is perpendicular on HL, and *b* is the vanishing point of *z* the roof of the church B. The light is parallel to the picture, and to the line RH; so that the shadow *x* of the point *g* is found by drawing *3x* through its seat parallel to HL, and *gx* parallel to HR cutting it in *x*. All the rays being parallel to RH, and H being the vanishing point of *ta* (the side of the house before the church) HR is the vanishing line of the plane made by the rays which pass through the line *ta*, and LR being the vanishing line of the church B; the shadow *tu* is cast on, R is the vanishing point of the common intersection of those two planes, that is of the shadow *tu* of the line *ta*; therefore the line *tu* is drawn through the point R, and not parallel to HR as *gx* for the shadow *3x*; through Q draw *us* for the continuation of the shadow *tu*, of *ta* on the top of the shed, and *sw* perpendicular to HL finishes the shadow of *ta* and the side of the house.

## E X A M P L E XLIX.

## P L A T E XXXII.

In this landscape the houses A, B, D, E have one side perpendicular to the picture, therefore vanishes at C, the center; the dotted lines drawn through the bottom of the houses is their seat, (which is even with the surface of the water) make every reflection as far below that line as the real object is above it, as appears by the Fig. 1, 2, 3, in the water answering the same figures above it; point O is the vanishing point for the boards F and its reflection *f*; the light is supposed coming from behind the picture, O is the vanishing point of the shadow on the ground, but the vanishing point of the rays of light are out of the plate, to shorten the shadows. Plate XXXIII. represents the same finished.

## E X A M P L E L.

## P L A T E XXXIV.

In this plate are several representations of balls or spheres; most of their sections being parallel to the picture are similar to their originals; and tho' the contour that should form the balls round are not so, yet their appearances are round to every spectator. That representations and their appearances may be different, is very evident, by what has been demonstrated at the end of the theory (See Plate XXXIX. Fig. 1.) where  $CD$  is the representation, and  $Cd$  the appearance; for unless the axis of the sphere pass through the spectator's eye, and center of the picture, the representation of it cannot be round, if according to the strict rules of perspective. Fig. 6. in this plate shews  $de$  for the representation of the line  $Dw$ , and  $c$  of point  $C$  (the center of  $Dw$ ) on the picture  $HK$ , but  $c$  on the line  $de$  is not in the middle. But  $b k$  the appearance of  $Dw$ , and  $i$  of  $C$  to a spectator's eye, placed as in the scheme,  $i$  appears to be the middle of  $b k$ .

## E X A M P L E LII.

## P L A T E XXXV.

Represents a landscape with a rising ground that ascends towards the horizon, and answers to Plate XXX. That in Plate XXXVI. answers to Plate XXXIII.

## E X A M P L E LIII.

## P L A T E XXXVII. Fig. 2.

Let  $AB$  be the horizontal line,  $C$  the center of the picture, and  $GD$  the ground line. Take  $J$  the middle of the line  $AB$  as diameter, and describe a semicircle  $AOB$ , at  $C$  raise  $CO$  perpendicular to  $AB$ , cutting the circumference at  $O$  point of sight: Let  $A$  be the vanishing point of  $Hg$ . To determine

termine the point  $g$ , take  $AO$  for a radius, describe the arch  $OU$ , and  $AU$  will be the distance; set any point  $G$  on the ground line, and draw  $GU$  cutting  $Hg$  in  $g$  the point sought: in this manner may be cut any line in the picture: if  $B$  is the vanishing point,  $F$  is the distance,  $BO$  being radius, and  $OF$  the arch; make  $HD$  equal to  $HG$ , draw  $HB$  and  $FD$ , cutting  $HB$  at  $d$ , then draw  $dA$ ,  $gB$  intersecting at  $b$ , and  $Hgb d$  is the perspective of a square, whose sides are equal to  $HG$  or  $DH$ , and the angle a right one, as  $AOB$ .

## E X A M P L E LIV.

P L A T E XXXVII. Fig. I.

In this example every thing standing as in the last, on the ground line set any measure given, as  $HD$  for the front of a building,  $IL$  the center part of it,  $K$  the middle of the pediment,  $MG$  its depth, and  $MH$  the distance the corner of that building is in the picture. Draw  $HF$ ,  $MU$  intersecting at  $b$ ; draw  $bB$ ,  $bA$ , and from the points  $I, K, L, D$ , draw lines to point  $F$ , cutting  $bB$  at  $i, k, l, d$ , and from the points  $M, N, G$  to  $U$  cutting  $bA$  at  $ng$ . To give the proper height of every parts of the building, produce  $bB$  to the ground line at  $P$ , make  $PQ$  perpendicular to  $GD$ , set on it the several dimensions, and on  $b, i, k, l, d, ng$  raise lines perpendicular to the ground line, and through every divisions on  $PQ$ , draw lines to  $B$  cutting the perpendiculars  $b, i, k, l, d$ , at  $b, r, x$ , and through the points  $b, R$  on  $b$ , draw lines to  $A$  cutting the perpendicular  $n$  at  $T$ , and  $g$  at  $V$ , join  $bTV$  for the roof. To find its vanishing point, make  $EA$  perpendicular to  $AB$ ; produce  $bT$ , cutting  $EA$  in  $E$  for the vanishing point of the side of the roof  $bT x u$ . If  $EA$  be continued below the horizontal line, and  $TV$  produced, their intersection will be the vanishing point for  $TV$ . To finish the pediment  $wfu$ , draw  $kA$ ,  $nB$  at their intersection  $s$ , raise a perpendicular to  $GD$ , draw  $TB$ , cutting it at  $y$ , then draw  $Aio$ ,  $Arw$ , make  $ow$  parallel to  $ir$ , draw  $oB$ ,  $wB$ , draw

draw a line through A and *l*, cutting *oB* at *z*; make *zu*, parallel to *wo*, cutting *wB* at *u*, through KF draw a line cutting *oz* at *e*, at that point raise a perpendicular to GD, and through *y* and A draw *yf*, cutting *ef* at *f*; then join *wfu*, draw *atB* (the top of the window) till it cuts *ir* at *t*, then draw *Atc* cutting *ow* at *c*, draw *cB* for the top of the window on that part of the building, proceed in the same manner for the under part of them; for the windows on the side F of the house, it is only using the point A instead of point B. These examples are sufficient for the young practitioner to draw landscapes, views, &c. &c. in perspective, if he has already acquired some skill in drawing, as by these rules he will be enabled to adjust and correct his designs, and be capable of performing them to the greatest nicety and exactness.
